A MEDICAL JOURNAL CONTAINING THE

FFICIAL RECORD OF THE PROCEEDINGS OF THE ASSOCIATION, AND THE PAPERS READ AT THE ANNUAL
MEETING, IN THE SEVERAL SECTIONS, TOGETHER WITH THE

MEDICAL LITERATURE OF THE PERIOD

EDITED FOR THE ASSOCIATION UNDER THE DIRECTION OF THE BOARD OF TRUSTEES

BY

GEORGE H. SIMMONS, M.D.

VOLUME XXXV 35
JULY—DECEMBER
1900

CHICAGO.
AMERICAN MEDICAL ASSOCIATION PRESS.
1900

"*The American Medical Association, though formally accepting and publishing the reports of the various Standing Committees (and Sections), holds itself wholly irresponsible for the opinions, theories or criticisms therein contained, except otherwise decided by special resolution.*"—TRANSACTIONS, 1851.

OFFICERS OF THE AMERICAN MEDICAL ASSOCIATION

1900-1901

GENERAL OFFICERS

President—Charles A. L. Reed	Cincinnati, Ohio
First Vice-President—A. W. Calhoun	Atlanta, Georgia
Second Vice-President—A. A. Woodhull, U.S.A.	Denver, Colorado
Third Vice-President—Philip Marvel	Atlantic City, New Jersey
Fourth Vice-President—Wm. E. Quine	Chicago, Illinois
Treasurer—Henry P. Newman	100 Washington St., Chicago, Illinois
Secretary—George H. Simmons	61 Market St., Chicago, Illinois
Assistant Secretary—Wm. Davis	St. Paul, Minnesota
Librarian—George W. Webster	Chicago, Illinois
Chairman Com. of Arrangements—John F. Fulton	St. Paul, Minnesota

BOARD OF TRUSTEES.

Alonzo Garcelon, Lewiston, Maine (President), 1901.
T. J. Happel, Trenton, Tenn., 1901.
I. N. Love, 4661 Maryland Ave., St. Louis, 1901.
E. E. Montgomery, 1715 Walnut St., Philadelphia, 1902.
H. L. E. Johnson, 1400 L St. N.W., Washington, D.C., 1902.
Joseph M. Mathews, Louisville, Ky., 1902.
Miles F. Porter, Ft. Wayne, Ind., 1903.
E. Fletcher Ingals, 36 Washington St., Chicago, 1903.
W. L. Rodman, 1626 Spruce St., Philadelphia, 1903.

JUDICIAL COUNCIL.

Term expires 1901: S. Bailey, Iowa; D. R. Brower, Illinois; N. S. Davis, Illinois; H. D. Didama, New York (Chairman); D. Mason, Washington; F. T. Rogers, Rhode Island; Milo B. Ward, Missouri. Term expires 1902: J. D. Griffith, Missouri; P. H. Bailhache, Marine-Hospital Service; J. E. Cook, Ohio; J. P. Lewis, Kansas; F. H. Wiggin, New York; J. W. Irwin, Kentucky; Walter Wyman, District of Columbia. Term expires 1903: James R. Guthrie, Iowa; G. B. Gillespie, Tennessee; R. C. Moore, Nebraska; Ida J. Heiberger, District of Columbia; John D. Roberts, Pennsylvania; Charles S. Rodman, Connecticut; S. L. Jepson, West Virginia.

SECTION OFFICERS

Officers of Sections, 1900-1901.

Practice of Medicine—Chairman, J. M. Anders, Philadelphia; Secretary, Wm. Britt Burns, Deckerville, Ark.

Obstetrics and Diseases of Women—Chairman, Henry P. Newman, Chicago; Secretary, C. L. Bonifield, Cincinnati, Ohio.

Surgery and Anatomy—Chairman, A. J. Ochsner, Chicago; Secretary, Martin B. Tinker, Philadelphia.

Hygiene and Sanitary Science—Chairman, Ernest Wende, Buffalo, N. Y.; Secretary, J. N. Hurty, Indianapolis, Ind.

Ophthalmology—Chairman, J. A. Lippincott, Pittsburg, Pa.; Secretary, E. C. Ellett, Memphis, Tenn.

Diseases of Children—Chairman, Samuel W. Kelley, Cleveland, Ohio; Secretary, Wm. E. Darnall, Atlantic City, N. J.

Stomatology—Chairman, R. R. Andrews, Cambridge, Mass.; Secretary, Eugene S. Talbot, Chicago.

Nervous and Mental Diseases—Chairman, H. A. Tomlinson, St. Peter, Minn.; Secretary, F. Savary Pearce, Philadelphia.

Cutaneous Medicine and Surgery—Chairman, W. L. Baum, Chicago; Secretary, R. R. Campbell, Chicago.

Laryngology and Otology—Chairman, John N. Mackenzie, Baltimore; Secretary, George C. Stout, Philadelphia.

Materia Medica, Pharmacy and Therapeutics—Chairman, N. S. Davis, Jr., Chicago; Secretary, J. N. Upshur, Richmond, Va.

Physiology and Dietetics—Chairman, Elmer Lee, New York City; Secretary, R. Harvey Cook, Oxford, Ohio.

Pathology and Bacteriology—Chairman, Ludvig Hektoen, Chicago: Secretary, Frank B. Wynn, Indianapolis, Ind.

General Executive Committee. 1900-1901.

Executive Council—Chairman, W. J. Mayo, Rochester, Minn.; Vice-Chairman, H. O. Walker, Detroit; Secretary, L. Duncan Bulkley, New York; Frank Billings, Chicago; B. Alex. Randall, Phila.

Practice of Medicine—S. A. Fiske, Denver; Frank Billings, Chicago; George Dock, Ann Arbor, Mich.

Obstetrics and Diseases of Women—Joseph Price, Philadelphia; A. H. Cordier, Kansas City; W. E. B. Davis, Birmingham, Ala.

Surgery and Anatomy—W. L. Rodman, Philadelphia; W. J. Mayo, Rochester, Minn.; H. O. Walker, Detroit, Mich.

Hygiene and Sanitary Science—Arthur R. Reynolds, Chicago; W. C. Woodward, Washington, D. C.

Ophthalmology—Harold Gifford, Omaha; Casey A. Wood, Chicago; H. V. Würdemann, Milwaukee, Wis.

Diseases of Children—J. P. Crozer Griffith, Philadelphia; H. E. Tuley, Louisville, Ky.; Edwin Rosenthal, Philadelphia.

Stomatology—A. E. Baldwin, Chicago; G. V. I. Brown, Milwaukee, Wis.; M. H. Fletcher, Cincinnati, Ohio.

Nervous and Mental Diseases—C. H. Hughes, St. Louis, Frederick Peterson, New York City: Hugh T. Patrick, Chicago, Ill.

Cutaneous Medicine and Surgery—A. W. Brayton, Indianapolis; W. T. Corlett, Cleveland; L. Duncan Bulkley, New York.

Laryngology and Otology—B. Alexander Randall, Philadelphia: Emil Mayer, New York City; Christian R. Holmes, Cincinnati.

Materia Medica, Pharmacy and Therapeutics—John V. Shoemaker, Philadelphia; Thos. Hunt Stucky, Louisville, Ky.; Leon L. Solomon, Louisville, Ky.

Physiology and Dietetics—Randall Hunt, Shreveport, La.: James Weir, Jr., Owensboro, Ky.; Winfield S. Hall, Chicago.

Pathology and Bacteriology—W. T. Howard, Jr., Cleveland: D. E. Salmon, Washington, D. C.: W. G. Spiller, Philadelphia.

Original Articles.

PAROXYSMAL TACHYCARDIA.*

JOSEPH M. PATTON, M.D.

Profesor of Internal Medicine, Chicago Policlinic; Professor of Physical Diagnosis, Medical Department University of Illinois.

CHICAGO.

It is not my purpose to undertake a semeiological discussion of the motor disturbances of the heart, but to ask your indulgence for a few moments' consideration of one of the two alterations of the cardiac rhythm which present definite features with sufficient constancy and regularity to have brought them almost within the category of the recognized diseases of the heart, where they probably belong, yet in which the failure, so far, to define their pathologic entity has relegated them to the class of so-called functional disorders of that organ. A full consideration of the semeiotics of these disorders—tachycardia and bradycardia—would involve a discussion of the innervation of the circulatory apparatus and its relation to rhythmic alterations in the heart's action, which would occupy more time than the limits of this paper will allow, as I simply wish to call your attention to some features of the first named of these alterations in the heart's rhythm, as illustrated in a typical instance of paroxysmal tachycardia.

I make premeditated use of the qualification, "paroxysmal," despite Allbutt's solecism—"as one of its (tachycardia's) eminent characteristics is its paroxysmal occurrence the addition of the qualification to its name is superfluous." If we accept his somewhat sarcastic arraignment of the use of the term "tachycardia" to denote various symptomatic states of increased rate of heart action, then we can consistently disclaim the term "paroxysmal." If, however, it is proper to use the term "spasmodic" as indicative of a form of asthma essentially different from other forms of asthmatic manifestations, it is equally appropriate to make use of the qualifying term, "paroxysmal," as indicative of a form of rapid heart essentially different from other forms in that, as described by Nothnagel, it comes on suddenly, lasts a few hours or days, and t [illegible] If with Anders we use the term [illegible] those neurotic instances of increase of the heart-rate such as occur in certain nervous conditions, with blood changes from toxic agencies, shock, fright, etc.; or if we use the term in reference to the symptomatic forms of increased heart-rate from the pressure of tumors from hemorrhage, from softening of the medulla or cord, from paralysis of the vagus due to tumors, aneurysms, or enlarged lymph-glands or from the various reflex causes, the necessity of some special designation for the form under consideration becomes apparent. It is evident that the use of the term "tachycardia" in relation to ordinary symptomatic forms of rapid heart must be more or less pedantic, as illustrated by Anders, who says that tachycardia may occur as a physiologic condition in certain people whose pulse may range from 90 to 100 beats per minute. Such use of the term seems somewhat arbitrary. We see at times, however, instances of a more or less persistent rapid heart in connection with hysteria and other neurotic states where the pulse-rate may be from 120 to 140 or 160, presenting marked variation in rate but not the paroxysmal feature peculiar to essential tachycardia and to which the application of the term "tachycardia" would seem to be justifiable.

In illustration of the striking difference between the clinical manifestations of ordinary forms of symptomatic heart-hurry and essential paroxysmal tachycardia I may cite the following case:

Mrs. M., aged 60 years, came to my office in December, 1898, saying she wished to consult me about her heart. She was a well-preserved woman of medium height, and rather stout, with a general appearance of good health. She stated that she had never been ill, with the exception of the ordinary sicknesses of childhood; that she had always been active and energetic in both domestic and social life, but had been obliged within the last two years to be careful in regard to physical exertion and diet, because of the "spells" with her heart which were becoming more frequent and persistent. She stated that these spells she had had at intervals for several years. At first they were infrequent and of short duration—an hour or two. During the last two years the attacks had become so frequent and persistent as to be present nearly one-third of the time, and lasted from half a day to two days at a time. While she was able to go about and attend to her ordinary duties even during an attack, she realized that she was becoming steadily more and more incapacitated, and this had alarmed her, particularly as she had taken various forms of treatment without any particular benefit.

She stated that she realized when an attack began and when it ended. With the beginning of an attack she felt a slight fluttering of her heart; during the attack she felt nervous and restless, and while conscious that the heart was beating rapidly there was no special feeling of discomfort, and at times she would forget all about it. Usually she slept well, though of late she had difficulty in getting to sleep when the attacks were on. When the attacks ceased she was conscious of a sudden check in the action of the heart and immediately felt relieved as of a nervous strain. She felt exhausted after an attack, in proportion to its length. She stated that she was then suffering from an attack which had begun on the previous day; that she had been down town for several hours before coming to see me and was somewhat fatigued. I felt her pulse. The artery was not well filled and the pulse was very compressible. The rate was 210 per minute. The heart-beat coincided with the radial pulse. The machine-like regularity of the hearts' action was strikingly characteristic. There was absolutely no variation in the rhythm. The heart sounds were weak and tick-tack in character, the second being, perhaps, a trifle higher in pitch than the first, though the two were remarkably alike in duration and pitch. There was no subjective or objective evidence of palpitation, tremor cordis, or delirium cordis. There were no cardiac murmurs, and the patient was not dyspneic. The visible and palpable area of impulse was somewhat increased in extent and displaced slightly to the left, but was weak and ill-defined. The left border of dulness was slightly displaced to the left. The apex impulse remained in the fifth interspace. The second pulmonic and aortic sounds were not intensified.

---

*Read before the Chicago Society of Internal Medicine, March 29, 1900.

The patient was seen at her residence the following morning. She stated that the attack had ceased about an hour before my arrival, and that except for her weakness she felt quite well. Her pulse was 70, perfectly regular, and the heart's action apparently normal.

The patient was under observation for three months during which period the attacks became of longer duration and left her weaker and with increasing dilatation of the heart. Upon one occasion I happened to have my fingers upon her radial pulse when one of the attacks terminated. There was a sudden cessation of the rapidly-running pulse, a very short pause, a strong, well-defined pulsation, followed immediately by a weaker one, and by the time I could apply my ear to the chest-wall of the heart was beating steadily at the rate of 70.

No substantial improvement was obtained by any method of treatment. The attacks increased in frequency and duration until they were on fully half the time. In the latter part of March, 1899, she had an attack lasting over four days. On the morning of the fifth day I found her much exhausted, dyspneic, and slightly cyanotic. There were edematous râles in the base of both lungs; the apex of the heart was outside of the mammilary line; the pulse-rate was 210 per minute but very feeble. It rapidly became imperceptible; the dyspnea and cyanosis increased and she died quietly with no evidence of suffering. A post-mortem examination was not obtained.

Tachycardia paroxysmalis, synchopexia, essential or recurrent tachycardia, heart-hurry, as it has been variously termed, was probably first noted by Catton. Watson, Williamson and others soon followed him. The name "tachycardia" was first used by Gerhardt, and the qualification, "paroxysmal," by Bouveret. Among the best descriptions of the condition are those of Martis and of Herringham. Prœbsting gave a detailed description of tachycardia, and Nothnagel described three cases in 1887. A number of observers subsequently followed with case reports. Some of the earlier observers appear not to have noted the essential features of the typical form, as, for instance, Fraentzel, who speaks of the "terrifying feeling of palpitation" accompanying the attacks.

Etiologically the observations of Œttinger appear to establish some hereditary influence. Males appear to be somewhat more frequently affected than females, and the attacks are most likely to appear between the ages of 30 and 50 years, though they may occur at any age. In seven of the fifty-three cases collected by Herringham the affection began in childhood. H. C. Wood, and Watson Williams have each reported instances of tachycardia in patients over eighty years of age. Various diseases have been described in association with tachycardia, though no etiologic connection has been established. Fright, shock, traumatism and various reflex causes have been associated with the onset of attacks; but the paroxysms generally appear to be, in typical cases, independent of such influences. At the same time, these various influences may unquestionably act as the immediate exciting cause of the paroxysms. Theoretically, the cause has been attributed to either paralysis of the pneumogastric, or to stimulation of the sympathetic nerves. Martis attributed the occurrence of tachycardia to sudden dilatation of the heart. As for disturbance or paralytic inhibition of the vagus, put forth by Tuczek as a cause of tachycardia, none of the results known to follow bulbar disease, pressure on the vagus from tumors or enlarged glands, nor experimental work indicate that such a high rate of action of the heart can be obtained from such sources. Synchronous inhibition of the vagus and stimulation of the accelerators may be admitted as possible causes but this would postulate some temporary bulbar change, so far impossible of demonstration—possibly a bulbospinal neurosis, as suggested by Debove and Boulay. You will recall that Talamon regarded the affection as epileptiform in nature. Perhaps some of our neurologically inclined members will inform us as to what that may mean.

Stimulation of the accelerators to the extent of overcoming vagus control, as suggested by Nothnagel, while favored by the character of the onset and termination of the attacks, is opposed by the total inability to produce any like effect by experimental stimulation. Certainly reflex irritations, which in some cases of tachycardia appear to be definite etiologic factors in the production of individual paroxysms, do not have the inherent power of instituting them. As far as the cardiac ganglia are concerned no definite changes have been demonstrated in them which are associated with tachycardia. Moreover, the researches of Gaskell and others would appear to prove that the ganglia are not sufficiently concerned in the dynamic properties of the heart to produce any such an effect as tachycardia. In regard to the effect of changes in blood-pressure from extensive dilatation of the venous or arterial systems, such alterations in the vascular tracts do not produce such a high rate of heart-beat. In collapse from vasomotor paresis, from hemorrhage, or from the sudden removal of large amounts of serous fluid we do not usually find a pulse-rate above 160-180 per minute. In those cases of rapid heart associated with hysteria and kindred states we find the pulse-rate subsiding during sleep or during the administration of an anesthetic.

Although paroxysmal tachycardia is not associated with any clinically demonstrable disease of the heart, in the six cases which have come to post-mortem there has been shown myocardial disease in three, and if we consider that in those analogous disturbances of cardiac rhythm—tremor cordis and delirium cordi—there is practically always some form of myocardial disease present, we may admit that West's opinion, that the lesion of tachycardia is in the myocardium, is not without some force. Still, the failure to demonstrate some fault in the nerve-supply of the heart does not prove that such does not exist. The great frequency of myocardial disease and the great infrequency of tachycardia show the latter not to be dependent on the former alone. Nevertheless, myocardial changes may be a necessary, if not a principal, factor in the production of tachycardia, at least so far as modifying the inherent automatic and co-ordinate action of the myocardium is concerned. In a heart-muscle which has undergone changes ordinarily not productive of clinical, or possibly even of pathologic, evidences of disease, a sudden variation of the usual conditions of circulation or of innervation or both might be productive of such manifestations as tachycardia.

In a case recently under treatment, in a woman 57 years old, with moderate arteriosclerosis but with a previous record of good health, a primary attack of angina pectoris instituted a tachycardia wih a pulse-rate of over 200 per minute which continued until her death ten days later. At first there was marked delirium cordis; and pronounced irregularity was a feature until death. The attack was followed by embolic obstruction of the left peroneal artery. There was, probably, in this case, some obstruction of the coronary circulation which caused at once the angina and the tachycardia.

It would appear that under certain unknown conditions of the heart, tachycardia may occur more or less as the result of causes extraneous to the heart itself. The following case may be cited in illustration:

The patient was a male, 50 years old, a carriage builder by occupation. His previous health was good. On one or two occasions he had transient attacks of rapid heart action, but paid no attention to them. His arteries were atheromatous and his heart slightly hypertrophied. In ———, 189—, he was under my care for relapsing typhoid fever. The temperature was never very high, and the pulse rarely above 90, the average pulse-rate being from 70 to 84. There was considerable delirium and marked emaciation. The bowels were alternately constipated and loose. During the sixth week of the fever the pulse had averaged from 70 to 74 per minute and the delirium had been absent. One morning I was sent for about 9 o'clock. I found his pulse-rate 260 per minute, perfectly regular and typical of the pulse-rate of paroxysmal tachycardia. There was no palpitation, no dyspnea, no distress. His mind was perfectly clear. He said that the attack had begun very suddenly about an hour before my arrival, and that while he was conscious of the rapid action of his heart and felt nervous and irritable he was not suffering. I found that on the day before he had eaten considerably more than usual and that his bowels had not moved since early the previous morning. I ordered a saline laxative, this to be followed by an enema. Four hours later I saw him again and found his pulse was steady, regular and beating at 70 per minute. The attack had ceased abruptly two hours previously and shortly after a copious evacuation from his bowels. The patient made a slow but uneventful recovery, and has since been in good health.

This case and the one first cited illustrate typical forms of paroxysmal tachycardia. The more I have considered them the more impressed I have become with the belief that whether there may be involved in the production of the paroxysm, abnormalities of the cerebral cortex, mesocephalon, bulb, vagi, accelerators or cardiac ganglia, or whether anemic areas or eccentric irritations are involved in the production of the attacks, there probably is present some condition of the heart muscle in which temporary interference with its blood-supply (ischemia) renders unstable the inherent power of co-ordinate action and automatic contraction peculiar to the myocardium.

In the morbid anatomy of this affection there is nothing definite to consider. The symptomatology is already sufficiently covered in the recital of the above cases. The essential features are: the sudden onset, the great rapidity of the heart's action, and its machine-like regularity; the absence of palpitation and dyspnea, and the abrupt ending of the paroxysm. Such subjective sensations as pain in the chest, uneasiness, numbness, tingling, or consciousness of motor disturbance of the heart may be present, but usually are not. Indeed their absence is rather one of the differential features between essential and symptomatic tachycardia. Rarely there may be carotid or jugular pulsation, but as a rule these, like dyspnea and cyanosis, are associated only with the cardiac dilatation which betokens the imminence of dissolution. Various symptoms have been detailed in the history of the cases that have been reported, but none of these are peculiar to tachycardia.

The prognosis is unfavorable in recurrent cases, and in all cases is uncertain. Recurrence usually becomes more frequent and the attacks prolonged until fatal dilatation of the heart occurs as in the case first cited. Herringham's statement, that the prognosis depends largely on the frequency and duration of the attacks, is true enough, but his remark, that few patients pass the age of fifty years, is not substantiated by the records. In some instances the attacks have grown more infrequent as the age of the patient advanced.

As to the treatment there is little to say. There being no specific indications, naturally the therapeutic management of these cases must be empirical, aside from the usual means applicable to any abnormal condition of the heart muscle and endocardium, or to any eccentric factors of which observation in the interval of the attacks may indicate some possible causal relationship. All the hygienic and other measures adapted to the therapeutic management of cardiopathic states in general are applicable in this connection; for even if no abnormal condition of the heart can be clinically made out we can not assume that the heart is healthy. The diet and exercise should be adjusted as in other cardiopathies. Eccentric sources of irritation should be searched for, especially in the intestinal tract. Autotoxic conditions should be avoided. During the attacks, if dilatation of the heart is increasing, digitalis should be given cautiously. As a rule it does not influence the pulse-rate for the better and its utility is doubtful. Stimulation of the vagi by pressure or electricity to their cervical portion is recommended, but has utterly failed at my hands. Compression of the chest as recommended by Rosenfeld gave the same result. It may be practiced by the patient, who fixes the feet against the bottom of the bed, applies his arms firmly to the sides of the chest and the forearms to the lower anterior portion of the chest wall; inspires deeply, fixes the glottis and makes strong expiratory efforts while pressing firmly against the chest with his arms.

Massage of the heart through the fourth and fifth interspaces seemed to me to increase the force of the heart's action but not to cause any change in the rate. Ice-bags to the precordium are recommended, but I have seen no benefit from their use.

In the case first cited, regulation of the diet, intestinal antisepsis and sodium bromid seemed to have a temporary beneficial effect. The attacks themselves were not affected in the least by any means employed. Patients with arteriosclerosis should be kept on moderate, continuous dosage of strychnia and sodium iodid, or, possibly nitrite of sodium, in order that the blood-supply to the heart muscle should be favored as much as possible. Every means should be adopted which is calculated to produce or maintain a better nutritive condition of the myocardium. Even if temporary ischemia of the heart muscle is not concerned in the production of the attack; and granting that no constant form of muscular degeneration or change is recognized as productive of or resultant from the attacks, we still have to confront the therapeutic problem of postponing the period of cardiac dilatation which ends the clinical history of these cases and to that end must bend every effort toward maintaining the integrity of the myocardium.

DISCUSSION.

Dr. Geo. W. Webster—We are to be congratulated on having our attention called to one point particularly in this paper, and that is the nature of essential tachycardia. This term has been in use in medical literature for something like 20 years, and recently there has been a tendency on the part of the profession to use the term as a synonym for increased cardiac frequency. This is, as Dr. Patton has said, pedantic, and it should not under any circumstances be so used. There seems to be no unanimity of opinion among authorities in regard to its etiology, its classification, its pathology, or its treatment. Whittaker, for instance, says that it is always a symptom and never a disease. Allbutt, with equal dogmatism, says it is always a disease and not a symptom.

In regard to its cause, some authorities maintain that the disease is in the cardiac ganglia, and there only; others maintain that the disease is a pure neurosis; and still others that it is toxic or reflex. For all of these statements there seem to be reasonable grounds. There are well-authenticated cases of typical paroxysmal tachycardia, where after the removal of a tapeworm, for instance, these attacks have never recurred. Some regard the cause as a myocarditis, or rather as a dilatation of the heart; for instance, Whittaker says that the affection is now regarded as due to a dilatation of the heart; others regard it as a pure neurosis. Similarly, with reference to its pathology authorities are not agreed. It seems to me that we should be very careful about the use of the term "'tachycardia;" we ought to limit it as Dr. Patton has carefully done, using it provisionally to designate those diseases, or, if you choose, those typical recurrent symptom-groups characterized by a sudden onset, where the pulse-rate suddenly jumps the normal to 120, 160, 180, 200, or even 250 or more in the minute; to indicate that the attack is never accompanied by palpitation; that there is perfect rhythm, both of time and of volume; that there is low peripheral resistance and low blood-pressure; that the attacks terminate as suddenly as they begin, and leave no apparent effects beyond a possible slight dilatation and fatigue of the heart, consequent upon the increased amount of work which it has been called upon to perform. If used in this way, as a provisional term, and not simply to indicate heart-hurry in those cases, like exophthalmic goiter, or tabes dorsalis, where there is a constant increase in frequency of pulse, nor as some recent writers use the term, to indicate simply hurry of the heart in such diseases as chronic tuberculosis, such use will serve to facilitate our thinking in regard to tachycardia, and will put no bar in the way of progress in the investigation of its pathology. It should be limited to a definite symptom-group.

Dr. Edward F. Wells—The subject of tachycardia is an extremely interesting one, and has been well presented by Dr. Patton in his paper this evening. There can be no doubt that the term, where applied to a morbid entity, should be strictly limited, and that the disease is an essential one. The heart-hurry accompanying toxemia, or that accompanying such a disease as exophthalmic goiter, is entirely different in character from that due to essential tachycardia. I doubt, however, the advantage of limiting the disease definition as closely as has been done by some systematic writers and, incidentally, by Dr. Patton. I believe that recurrence is not necessarily a part of the clinical history of the disease. To be sure, we can never say in any case of tachycardia that the patient may not have had previous attacks, or that subsequent attacks may not occur; but I am inclined to think, as the result of my personal experience, that a single attack or paroxysm of tachycardia, coming on suddenly and stopping suddenly, with great rapidity of the heart's action, without palpitation, but with a sense of precordial discomfort or distress, and without greatly prostrating the patient, is not so very rare, and is really the same disease as that which is known as recurrent paroxysmal tachycardia. I have under observation several patients who have had or are having attacks of heart-hurry, and, as illustrating the points of essential difference of the heart-hurry in the paroxysmal tachycardia under consideration and in tachycardia in some other diseases, I have several tracings (which he exhibited). The first tracing is from a case of exophthalmic goiter in which the pulse was very rapid. It is a characteristic tracing. The next tracing is from a case of intestinal toxemia. The symptoms of toxemia and the heart-hurry came on rapidly, not suddenly. In this case the toxemia and extreme frequency of the pulse was easily and completely relieved. I wish to call your attention now to the tracing from a case of paroxysmal tachycardia, with recurrent attacks, and you will notice that the characteristics differ radically from the other types. These tracings are important in the study of tachycardia and show minute details which can not be recognized by the finger and enable us to leisurely compare them with others. We may not be able to say that obvious or gross disease of the heart is necessarily accompanied by tachycardia, or that tachycardia accompanies any specific organic disease of the heart; still the fact remains that these patients do complain, it may be indefinitely, of their hearts. This patient, a woman, came to me several years ago for the express purpose of having her heart examined. At the time she was 40 years of age and there was no history of anything more than a vague sense of precordial distress; certainly no mention was made of rapidity of the heart. I took numerous tracings early in the history of the case, and one quite recently. The ordinary normal character of the pulse is shown. There are no heart murmurs present. I have seen her several times during or immediately following the attacks of tachycardia, and at these times the right ventricle is evidently dilated. At other times when in normal health there is no evidence of enlargement of the heart.

As illustrating another feature I wish to give briefly the history of a woman 65 years of age, who has been under my observation for some time, and in whose case there was present, in 1895, a heart murmur. I do not recall the nature of the heart murmur, but the heart was regular in its action, as is well shown in one of these tracings (exhibiting tracing). This woman one morning had some discomfort in the region of the heart. She had been entertaining some visitors; took her morning carriage ride, but in the afternoon she sent for me, saying she was not feeling well. She was up and about, but somewhat restless, and complained of a slight uncomfortable sensation in the cardiac region. Her pulse was beating more than 206 times per minute, as shown in this sphygmogram; the other tracings show the character of the pulse before and after the paroxysm. The beginning of the attack was sudden; the end was equally sudden, and there has been no recurrence and no history of an previous attack.

Another woman, 50 years of age, gave a history of frequent headaches and jaundice. Cardiac arrhythmia had been noted some years before, and is yet present. I show you the tracings in this case before and during an attack of heart-hurry, and immediately following. I have tracings in which the irregularity of the heart is shown. The attack in this case followed an attempt to ride a bicycle, but there was a history of some previous attacks which were very similar, so far as sensations were concerned, but no account had been made of the pulse.

The hurry of the heart accompanying hysteria is well shown in this tracing (exhibiting tracing), although it is not so marked as in some other cases I have seen. In hysterical cases I think the rule is for the pulse to gradually become more rapid.

Several years ago I saw a gentleman, 35 years of age, who, during satisfactory convalescence from typhoid fever, picked up the nurse's record, and in looking over it thought it would be a good plan to count his own pulse. He did so, and found it reached 100, although during the attack of typhoid fever his pulse did not exceed 90. He called his wife and said there was something the matter with him, and when I saw him later his heart was beating 180 times per minute, and his face was bathed in cold perspiration—clearly a nervous state. A hypodermic injection of morphia relieved the condition, likewise his anxiety.

Repeating, I wish to state that we may have a tachycardia that is identical with paroxysmal tachycardia without recurrence, and these cases should be classed with those of essential tachycardia. I simply object to the term "recurrent" as a necessary part of the title and applicable to this affection.

Dr. Geo. W. McCaskey, of Fort Wayne, Ind.—In thinking over the anatomico-physiologic mechanism of the circulation during the reading of this interesting paper, it has occurred to me that there are four possible causes for the condition we are discussing: 1, lesions in the central nervous system; 2, lesions in the intracardiac nervous mechanism; 3, lesions in the peripheral nervous system in the way of so-called reflex irritations; 4, disturbances in the blood itself. The opinion is held by some that these attacks are due to some toxic influence; but in the cases described by Dr. Patton, it seems to me that the toxic origin is entirely out of the question, unless we can assume that the tachycardia is brought about by some sort of cumulative or explosive action upon the nervous mechanism of the heart—which is perhaps possible. It seems clear to me that the essential condition at the time of these attacks must reside in the nervous system. I am not prepared to discuss the three other possibilities, but simply mention them to say that I am inclined to think all of them apply to different cases of paroxysmal tachycardia, the pathology of which varies greatly in different cases.

I would call attention to one condition which has been referred to by a previous speaker, and which may possibly explain some of the cases, and that is the sudden alteration in the arterial tension. At the present time I am studying a case very carefully which was referred to me by a colleague. The patient has had sudden attacks of bradycardia, followed by tachycardia. These attacks are periodic in character; they are not produced by exercise. The patient can lift weights or run upstairs without causing attacks, and upon auscultation and percussion there is no evidence of any cardiac disturbance. I believe the case is one of neuropathic angina, so-called by Landouzy. The pulse was as low as 25 or 30 on some occasions. The attack of bradycardia was doubtless due to some unknown cause which produced increased arterial tension. The attacks were regularly periodic—a phenomenon which does not pertain to true angina. I prescribed nitrite of amyl. She crushed one of the capsules, inhaled it, and the first inspiration aborted the attack, and this has been the result ever since. Here is an instance where a sudden alteration in arterial tension produced bradycardia which, when the nerve-centers became apparently exhausted, was followed by lowered arterial tension and tachycardia. It still remains for us to explain the lowered arterial tension in such cases.

Dr. N. S. Davis, Jr.—The tracings of Dr. Wells illustrate well a feature which I have observed in my own practice. It is the effect of respiration upon the heart's action, the production of a noticeable wave in the respiratory line of the tracing. The commoner causes of a rapid heart's action do not cause this. But in essential tachycardia it has been present in all cases which have come under my notice. Essential tachycardia is described as a non-structural disease of the heart, and it is usually supposed not to be associated with valvular disease. There is no reason why it should not be. The following case illustrates the possible coincidence of both conditions. This case I have seen several times during the last two years. The patient, who comes from Wisconsin, has had many attacks of what appear to be in every respect attacks of essential tachycardia. The attacks have recurred very many times. He has a well but not perfectly compensated chronic valvular disease of the heart. The attacks of tachycardia come on without any discoverable cause, and they cease with the suddenness which is peculiar to essential tachycardia. I consider it a case of chronic valvular disease of the heart complicated by the phenomenon of recurrent essential tachycardia.

Dr. Patton—In regard to the remarks of Dr. Webster as to the unqualified use of the term "tachycardia," he misunderstood me slightly. I did not intend to make the point that the term "tachycardia" should not be used except in association with essential tachycardia. We must have some term by which we can describe the heart's action in such cases as we have associated with exophthalmic goiter, hysteria, etc. Where the pulse-rate is 200 or over I do not know how we can avoid the use of the term "tachycardia." If we do not use it we have to use a word which will mean the same thing. I objected to the term as it is used by Anders. The use of the qualifying term "paroxysmal" is not only justified but necessary in relation to distinct paroxysmal attacks. They are essentially different from the symptomatic forms. We ought not to use the unqualified term "tachycardia" to cover the whole field.

In regard to the case of tachycardia mentioned by Dr. Webster as being associated with tapeworm, it is quite possible, yet I do not believe it proves that the typical attack was due solely to the tapeworm. There must be some cardiac disturbance which will allow of the manifestation of such a condition. We have tapeworms and tapeworms, and we rarely see attacks of tachycardia associated with the existence or presence of tapeworm.

In regard to Dr. Wells' objection to the use of the term "recurrent," he will find in reading my paper that I have not used it at all except in connection with various other terms to describe the disease. It has not been used as one of the essential features of the attack. I have merely used the term "paroxysmal" as indicative of an attack that comes on as a paroxysm, continues for an definite period, ceases suddenly, and that may or may not be recurrent.

With reference to the causes mentioned by Dr. McCaskey, he has, of course, given the principal channels through which such an effect might occur.

In regard to vasomotor changes, sudden variation in blood-pressure, etc., this is a theory to which Allbutt is especially partial, but he has not been able to find sufficient reason to sustain it. From extensive dilatation of the vessels in the splanchnic area we do not get typical attacks of tachycardia. We get a rapid pulse-rate. I saw a man in collapse the other day from vasomotor paresis; he came very near dying. I saw another man who died from vasomotor paresis. The heart-rate in neither of these cases was above 190; one was 175, and the other 190. Fatal vasomotor paresis does not cause a pulse-rate of over 200; as a rule, it is seldom that point is reached. It comes on gradually as the case develops. I do not think we can explain essential paroxysmal tachycardia by vasomotor paresis, or through changes in blood-pressure due to vasomotor influences, because they require more time for their development; they do not recover so abruptly; there is more variation in the rhythm and in the force of the pulse. There is certainly a variation in the force, if not in the rhythm, in all cases of rapid heart due to nervous causes.

I was much interested in the experimental work of Dr. Matthews, and, as far as I can see that they have application to this discussion, they would bear out the theory that typical essential tachycardia is due to some intracardiac cause. It has a sudden beginning, a sudden cessation, irrespective of the blood-pressure. The mechanical rate at which the heart works and the altered rhythm are peculiar features of this kind of an attack, for, if arrhythmia be present it is likely to take the form of allorrhythmia. In the case cited in the paper, where a woman died during an atypical attack of tachycardia, the attack began as an angina; there was an allorrhythmic condition which would be very much like what Dr. Matthews has produced in his experimental work on the heart, the regular departure and regular resumption of certain rates. This is not usually seen in attacks of essential tachycardia, but its occurrence may take place in connection with tachycardia under certain conditions of circulation in the heart muscle.

As far as the cause is concerned, the possible influence of vasomotor changes, central nervous condition, abnormalities of the cardiac ganglion, etc., must be borne in mind. We must have something wrong with the cardiac muscle. We have cardiac muscular disease in practically all of these cases, but there is something else; whether there is a change in the blood-pressure in the heart muscle, resulting in a temporary ischemia, or whether the condition is due to some poisoning of heart muscle, I do not know; but I am convinced that there is something of that kind aside from extraneous causes affecting the heart muscle.

The case cited by Dr. Davis is interesting from a clinical standpoint. Practically all authorities are agreed that left-sided valvular disease may be associated with attacks of essential tachycardia. The valvular disease is not regarded in any sense as a cause, and should not be, except in so far that it might result in myocardial changes which would render the heart more susceptible to the other unknown causes which result in the paroxysmal. It is interesting, however, to have a record of the association of the two conditions.

EXPERIMENTAL AND CLINICAL NOTES ON THE SUBARACHNOID SPACE.*

DUDLEY TAIT, M.D., AND GUIDO CAGLIERI, M.D.
SAN FRANCISCO, CAL.

From the exclusive domain of anatomy and physiology the meningeal route has made its way through the work of clinicians, to the sphere of practical medicine and surgery. To Quincke is due the credit of having demonstarted the innocuousness of subarachnoid lumbar puncture, its facility of execution, and the harmlessness of the withdrawal of a considerable amount of cerebrospinal fluid. Soon after Quincke made his original communication concerning "lumbal puncture," scores of physicians, in their enthusiasm for this new mode of relieving intradural pressure, predicted the curability of many diseases of the cerebrospinal system, previously deemed hopeless. In epilepsy, tuberculous meningitis and general paralysis many expected wonderful results. The German school, for example, singularly oblivious to the diffuse and deep cellular lesions present in tuberculosis of the meninges—the best known of all meningeal infections—adopted lumbar puncture as a logical and valuable therapeutic measure. A few doubtful cases of temporary amelioration in tuberculous meningitis were first reported. Then followed a long series of dismal failures. To-day, no one seriously contends that meningitis, especially of the tuberculous variety, can be cured by simply relieving pressure—decompression—and when we recall the extent of the bacillary lesions, the constant morbid changes in the nerve tissue—cerebral and medullary—subjacent to the meninges, and particularly when we consider the anatomy of the subarachnoid space, it seems almost incomprehensible that eminent surgeons in Europe and America should have proposed drainage of the lateral ventricles as a means of combating tuberculous meningitis. This procedure, first suggested by Wernicke (1881) and Zenner (1886), and adopted later by von Bergmann (1887), Keen (1886) and others, is not in accordance with either the clinical or the pathologic findings, as it is well established that the softening noted post-mortem in cases of tuberculous meningitis is due principally to an inflammatory process, and not to increased intraventricular pressure, which in reality plays a secondary part in the production of coma, and the failure of the cardio-respiratory action. Some physicians have argued from the analogy of tuberculous meningitis to tuberculous peritonitis that drainage ought to do good in the former condition since it does in the latter. These authorities forget that the lesions under discussion are very different, and consequently there is no real analogy to guide us.

In the present communication we do not deem it necessary to review the subject from a historic or biographic standpoint, except to establish beyond possible controversy the question of priority in cocain analgesia by the spinal route. To an American, J. Leonard Corning,[1] belongs the credit of having first suggested and carried out, both in animals and in the human subject, spinal analgesia by means of cocain injected into the lower dorsal region. Corning,[2] although his reasoning was manifestly unsound regarding the mode of action of the analgesic substance, nevertheless succeeded in obtaining analgesia of the lower limbs, scrotum, penis and lumbar regions, both in the dog and in man. He also mentioned the possibilities of this method of analgesia in genito-urinary and other branches of surgery.

Ziemssen (1893) was the first to suggest injections of diverse medicaments by lumbar puncture. Sicard was the first, however, to carry out this plan. This clever investigator began his studies in this domain as early as 1897. His first communication to the Biological Society of Paris was made in April, 1898, whereas Jacob, working in the laboratory of Professor Leyden, of Berlin, published his first report a month later. Sicard was also the first to use tetanus antitoxin and saline solution in the subarachnoid space. While great credit is unquestionably due Bier for calling attention to the analgesic properties of cocain by lumbar puncture, it should be remembered that his work comprised little more than the perfecting of Corning's technique in accordance with Sicard's experimental studies. Councilman, Mallory, and Wright (1898), of Boston, in their remarkable report on cerebrospinal meningitis, were among the first to utilize the subarachnoid space for the bacteriologic study of meningeal infections.

A review of general literature shows that all are agreed on the diagnostic value of the study of cerebrospinal fluid. It is indispensable in cases of meningitis, and may render valuable assistance in the differentiation of cerebral lesions and neoplasms, as is well illustrated by a case of cerebral actinomycosis correctly diagnosed by Monod and Sicard. In tuberculous meningitis, especially in circumscribed tubercles, the bacillus is found, by lumbar puncture, in 25 per cent. of the cases, according to the statistics of Leuhartz and Stadelmann.

---

*Read before the Medical Society of the State of California, San Francisco, April 17-19, 1900.

[1] Intradermic infiltration of cocain was used by Reclus in several hundred operations, minor and capital, before Schleich advocated this method of analgesia. The method of cocainization known in Europe as Kummer's—in which the field of operation is shut off by means of an elastic band—was made known and used by Corning as early as 1884. E. Hoffman (Deutsche Med. Woch., 1886) attributed "the essential advancement in the application of cocain for local anesthetic purposes" to Corning's discovery. Harvey Cushing (Annals of Surgery, Jan., 1900) erroneously states that Corning introduced cocainization of main nerve trunks. This method was the result of experiments made in 1886 by Feinberg, Kochs and U. Mosso. Krugius of Helsingfors, after whom the method is named, was the first (1894) to make use of these experiments. Cushing's error is probably due to the fact that Koch's work was reviewed (N. Y. Med. Jour., Jan. 22, 1897) by Corning.

[2] New York Med. Jour., Oct. 31, 1885.

The present communication is but a résumé of the work which has engaged our attention during several months. In the study of the subarachnoid space we have endeavored to elucidate certain doubtful points and have sought to make some practical deductions therefrom.

The subarachnoid space may be reached by several routes: 1. By trephining the skull. 2. The atlo-occipital route followed by Magendie in demonstrating the constant presence of cerebrospinal fluid. 3. The dorsal route, with or without laminectomy. 4. The sacrolumbar route. 5.Through the central spinal canal. The second, third, and fifth routes are seldom used, on account of the difficulty and danger encountered. In six out of seven cadavers we found the dorsal route accessible as high as the sixth space, without preliminary laminectomy. 6. The cervical route.

We found the sixth cervical space a sure and extremely easy route in the human being. We first tried this route on the cadaver, by injecting colored fluids, without previously having incised the skin, and obtained uniformly satisfactory results. The route most commonly adopted is the lumbar or sacrolumbar. We find the latter preferable in animals, and the third lumbar space the most practical in the human being.

The technique of lumbar puncture is well known, and is usually described in text-books. We desire, nevertheless, to call attention to a few points of interest, if not of value: 1. The distance to be traversed by the point of the needle is generally given as 7 to 8 cm. We have never found the distance so great as 8 cm., even in obese patients, but most invariably 6.5 to 7 cm. In two cases of adults, the distance was 5.5 cm. 2. The smaller the caliber of the needle, the slower, and therefore the safer, the procedure. The rapid introduction of 2 c.c. of liquid, in one of our patients produced considerable shock. 3. By first withdrawing a small amount of cerebrospinal fluid, one is certain of making the injection within the canal. 4. Slow aspiration of the fluid, contrary to the opinion of German authorities, does not induce any untoward symptoms. 5. Lumbar puncture may be rendered painless, and extremely easy, by injecting a few drops of Schleich's mixture into the skin and subjacent soft parts. By this simple plan, the sudden start of the patient will be prevented, and the relations of the osseous parts will thus remain undisturbed.

CEREBROSPINAL FLUID.

In this part of our investigations, a large unmber of animals—guinea-pigs, rabbits, cats, dogs, and even horses were used for experimental purposes, and a series of cadavers served to acquaint us with the intricacies of the subarachnoid space. Whenever feasible, the technique adopted in animals was as near as possible that followed in the human being, without preliminary laminectomy. Several patients subjected to lumbar puncture for therapeutic purposes were utilized to clear up doubtful points relating to the physiology of the subarachnoid space, and furnished valuable data. The cerebrospinal fluid resembles no other organic fluid. Our knowledge of its origin and mode of secretion and resorption is very incomplete. Anatomists compare the subarachnoid space to a serous cavity, to an immense lymph sac into which empty the cerebrospinal perivascular lymphatic vessels. Hence the important rôle ascribed to the lymphatics in the evolution of infectious meningitis. Against this classic opinion may be cited a long series of facts which compel us to change most radically our conception of the cerebrospinal fluid, its nature and rôle in the various infections. The normal cerebrospinal fluid possesses none of the chemical properties of lymph. It contains no histologic elements, no albumin, no leucocytes, no red corpuscles, no fibrogenous factors, nor fibrin ferment. In only one of our cases, which had been previously subjected to an injection of iodid of potassium, did we find a few leucocytes. Widal and Sicard demonstrated that in the course of typhoid infection or immunization, the cerebrospinal fluid does not possess agglutinating and preventive properties, in contradistinction to the secretions of serous membranes—peritoneum and pleura. Sicard showed that, unlike blood, the cerebrospinal fluid does not coagulate the non-spontaneously coagulating organic liquids, hydrocele fluid, for example. It is an excellent medium for the preservation of leucocytes, the latter retaining their ameboid movements and chemiotaxic properties. It only dissolves the red corpuscles after considerable time—*in vitro*. Artificial—medicinal—increase of arterial pressure does not augment the secretion of cerebrospinal fluid. On the contrary, direct increase of pressure by intravenous injection of saline solution, produces a noticeable increase, as the following experiment goes to prove: In a dog of 20 kilos, a fine needle was introduced in the lumbar subarachnoid space. After 10 c.c. had escaped, the fluid flowed very slowly—one drop every two seconds. 200 c.c. of salt solution was then injected into the femoral vein. The flow of cerebrospinal fluid showed an increase within ten minutes. In a series of patients we made lumbar punctures after having given by mouth or subcutaneously, repeated doses of salicylates, antipyrin, cyanid of mercury and potassium iodid and in no case was the drug found in the cerebrospinal fluid; whereas, urinary analysis invariably gave a positive result. In a dog of 15 kilos an intravenous injection of 5 c.c. of 1 per cent. solution of mercuric cyanid caused death within three minutes. Even under these exceptional circumstances, the cerebrospinal fluid showed no trace of the toxic substances.

On the other hand absorption and elimination occur when chemical substances are injected directly into the subarachnoid space. This was confirmed by experiments in animals and also in our work on man.

These facts prove conclusively that the osmotic current exists in only one direction: *there is exosmosis, but no endosmosis.* (Sicard.)

Considerable knowledge may be derived from the careful study of the mode of diffusion of the cerebrospinal fluid, under various conditions. In our work we employed insoluble colored mixtures, which enabled us to note with accuracy and facility both the microscopic and the macroscopic results in the different regions involved.

Briefly stated, the plan pursued was [illegible] foll[illegible] After having located accurately the vari[illegible] fine needle was introduced into the [illegible] of the lumbar region, and a mixture of carmin and saline solution, or a dilution of common washing blue—ferrocyanid and ferricyanid—injected, in variable quantities, with or without pressure, according to the object of the experiment. The results were as follows: When injected without pressure, the colored fluid stains the space at the point of injection, and then diffuses in all directions, ascending and descending, following the meningeal prolongations along the spinal nerves, to the intravertebral foramina, where it stops abruptly.

The extent and rapidity of diffusion are influenced by several factors; the amount, composition, density of the liquid, and principally the pressure under which the liquid is injected. If 1 c.c. of the blue mixture be slowly injected into a rabbit weighing 900 grams, it ascends rapidly, and if the animal be killed after ten hours, the colored fluid will be found around the medulla oblongata, and at the base of the brain. If the same amount of colored fluid be injected under considerable pressure, and the animal sacrificed after twenty-four hours, the fluid will be found over a much more extensive area; diffusing from the spinal subarachnoid space through the foramen of Magendie to the fourth ventricle, through the *iter a tertio* to the third ventricle, and finally to the cortex of the brain. We found that when 5 c.c. of the colored fluid was injected under great pressure in the lumbar space, the diffusion occurred instantaneously, and the color of the animal's eye recalled, in certain cases, the substance used.

Example illustrating the course pursued by the fluid from lumbar space to cortex of the brain: Rabbit, 850 grams. Preliminary trephining of the skull in the temporal region; injection of 10 c.c. of blue mixture in the lumbar space; time occupied, three minutes. After 2 c.c. had been injected the brain bulged through the trephined opening, and finally burst, the colored fluid escaping through the rent. Death occurred four minutes later. The inverse experiment was made by injecting the fluid directly into the lateral ventricles, but has not as yet given definite results. Improved technique will undoubtedly confirm the facts noted above. Our best specimens were obtained by means of injections made under a considerable pressure, death in some cases ensuing during, or shortly after the operation.

Post-Mortem Findings.—The necropsies of a long list of rabbits so treated showed the following conditions: The pia-arachnoid is colored in its entire course along the cord and brain, continuing along the sheath of the auditory, facial and optic nerves, and also following the prolongations of the olfactory through the cribriform plate of the ethmoid. On the optic nerves, the stain follows the meningeal sheath and generally stops at the junction with the sclerotic. In several of our specimens, however, the colored material followed a course similar—inversely—to that of the diplococcus in some cases of cerebrospinal meningitis, i. e., involved the sclerotic, choroid, papilla, and retina. We have never found the cornea stained. Microscopic sections of the brain and cord show the course followed by the colored fluid and its relations to the perivascular sheath. In several of the forced injections the colored fluid was found in the lungs, and from numerous necropsies we satisfied ourselves that it had escaped from the subarachnoid space, by the blood-stream, thus invalidating the views of Foster, who describes the escape of cerebrospinal fluid as occurring along the tubular prolongations of the pial membranes that accompany the cranial and spinal nerves to the general lymphatics.

The study of the numerous specimens mentioned above is of considerable interest in reference to the origin and evolution of meningeal infections. For instance, they explain very lucidly how tubercle bacilli, which are so frequently found in the tonsils, adenoids and nose, may easily reach the subarachnoid space, independently of the lymphatics, through the cribriform plate of the ethmoid, or the aqueductus Fallopii. The part played by the cerebrospinal fluid in the dissemination of the agent of infection is also made very clear. The same observation holds good in regard to infective lesions involving the cavities contiguous to the subarachnoid space—eye and ear. Another fact of great pathologic importance noted by Sicard is the insignificant rôle of the lymphatics in the origin of meningeal infections. As Sicard remarks, it is difficult to understand by what process the tubercle bacillus, escaping from a cervical or mediastinal gland can follow a retrograde course to the cerebral perivascular lymphatics. On the contrary, infections of hematogenous origin can easily occur, as Sicard's cases conclusively prove.

EXPERIMENTAL THERAPEUTICS AND PRACTICAL DEDUCTIONS.

The action of a drug varies with the route through which it is introduced into the body. Without apparent effect, when given by the mouth or subcutaneously, some substances, chemical or microbic, administered in like doses by the intravenous route, produce serious or even fatal effects. The intracerebral route, as was well illustrated by the interesting studies of Roux and Borel, and by Lesné and Sicard, requires a smaller dose to produce a fatal effect than any other route. The subarachnoid route occupies a position midway between the intracerebral and the intravenous routes (Sicard).

The difference in action of drugs, according to the route employed, can not be ascribed entirely to the degree of rapidity of its absorption and elimination. The tissue involved plays an undoubtedly important part. Each tissue reacts in a distinct manner. In regard to the brain it has been sugggested that the compresion and traumatism incidental to the intracerebral injections may explain in part the difference in effect, but Widal, Lesné and Sicard have proved that large quantities of saline solution can be injected into the brain without causing damage. Furthermore, intracerebral injections of tetanus antitoxin have proved to be harmless and nonproductive of appreciable lesions. These assertions were fully verified in the necropsy of a case of tetanus which we reported recently at the California Academy of Medicine.

In the following notes we relate our experience, in animals and the human being, with the subarachnoid space viewed as a therapeutic route. We sought to determine the degree of tolerance of this space for various toxic and non-toxic substances, some of which had not been used heretofore by this route, and to ascertain the action of said substances on the subjacent normal or pathologic nerve tissue.

In animals the drugs used were cocain, iodid of potassium, and cyanid of mercury.

Cocain.—In a dog of 10 kilos we injected, in the lumbar space, 1 c.c. of a 1 per cent. solution of cocain. Within three minutes, analgesia was noted on the lower limbs. At the expiration of five minutes complete analgesia—superficial and deep—was detected over the entire surface of the body, ears, nose and mouth. The animal presented a semiparetic condition of the hind legs for thirty minutes and then ran about as usual. The duration of analgesia was one hour and ten minutes. In a dog of 32 kilos, we injected rapidly, in the lumbar space, 2.5 c.c. of a 1 per cent. solution of cocain. Three minutes later analgesia was noted over the entire body, as in the previous experiment. The animal was greatly depressed, vomited, and was paralyzed in the hind legs. The paralytic condition ceased after the second day.

Mercury cyanid.—In a dog of 9 kilos, we injected 2 c.c. of a 1 per cent. solution. No pain was noted; mild paraplegia lasted fifteen minutes.

Iodid of potassium.—Our experiments with this drug were made with doses too small for any local effect. We found that to be of practical use by lumbar puncture, iodid of potassium must be considerably diluted. The saturated solution invariably produced most intense and prolonged pain.

INJECTIONS IN THE HUMAN BEING.

1. *By the cervical route.*—Remembering the innocuousness of intracerebral injections, and judging from the results of a series of punctures of the cord in animals, we inferred that the slight traumatism produced by the needle would not be followed by any untoward symptoms.

A. C., aged 49, had very painful chronic gonorrheal arthritis of the left knee and right wrist. We injected 1.5 c.c. of a 1 per cent. solution of cocain in the sixth cervical space, at a point .5 cm. from the median line. Eight minutes later, analgesia was noted from the toes to the level of the thyroid. On the limbs the analgesia was both superficial and deep. We were thus able to manipulate both of the diseased joints without inducing pain. Analgesia ceased within eight minutes.

A. L., aged 42, had rectal fistula and axillary adenitis. We injected 1 c.c. of a .5 per cent. solution of cocain, in the sixth cervical space. Fifteen minutes later we noticed very slight analgesia extending over the chest. This disappeared within five minutes. In neither of these two cases were there any disagreeable consequences. The procedure was painless. The second patient thirty minutes afterward walked a mile.

The third case was the same patient as in the second instance, and we injected, in the sixth cervical space, 3.5 c.c. of a .5 per cent. solution of cocain. The patient complained of a sharp pain in the left arm during the introduction of the needle. Cephalalgia, a feeling of intense heat over the entire body, copious perspiration and slight vomiting followed almost immediately. The pulse, temperature, respiration, and pupils remained unchanged. There was no analgesia even after one hour and twenty-five minutes. The patient then walked home—one mile—and, on the following day, he complained of slight headache and weakness in the legs. On the third day his condition was normal.

All of these patients were examined several weeks after the injection and found free from any possible complication.

2. *By the lumbar route.*—

I. T., aged 43, suffered from syphilitic myelitis, and was treated with a .8 c.c. injection of saturated solution of iodid of potassium, after we had withdrawn 1 c.c. of cerebrospinal fluid. Intense pain and burning were experienced immediately in both feet. Shortly afterward these symptoms were noted in the thighs, and the patient urinated involuntarily. The painful phenomena lasted six hours. The same patient subsequently received, by lumbar puncture, an injection of 3 c.c. of a 1 per cent. solution of cyanid of mercury. Nothing was noted until the fifth hour, which ushered in numbness and tingling of the lower limbs. Five hours later the patient had a gastric crisis, of greater severity than any previously experienced. No apparent amelioration resulted from the injections in this case. The gastric crises are now more frequent than formerly.

Subarachnoid injections of cocain were made in a series of cases requiring surgical intervention.

M. D., aged 54, suffering with necrosis of tibia, on Oct. 26, 1899, was injected with 1 c.c. of a .75 per cent. solution of cocain. No analgesia was noted before thirty-five minutes. Analgesia, both superficial and deep, was then well marked in the lower limbs. Osteotomy of the tibia was performed without causing either pain or discomfort. There were no unpleasant after-effects. Analgesia ceased after forty minutes.

O. L. had a pelvirectal fistula. We injected 1 c.c. of a .5 per cent. solution of cocain and no analgesia followed. Two hours later the patient complained of tingling and numbness in the legs. Investigation showed that the cocain solution was very old and had been boiled many times.

M. M., aged 26, had acute osteomyelitis of the tibia. We injected 1 c.c. of a 1 per cent. solution of cocain. Analgesia was first noted after twenty-five minutes. The patient also lost the muscular sense in the lower limbs. Amputation was made through the condyles after a thorough exploration of the knee-joint. No pain was noticed except when the popliteal nerve was pinched. The patient then said he felt the instrument but did not complain. The duration of the operation was thirty minutes, with no after-effects. Analgesia lasted fifty-five minutes.

M. U., aged 32, had a urethral fistula—membranous portion. We injected 1.5 c.c. of a .5 per cent. solution of cocain after having withdrawn 5 c.c. of cerebrospinal fluid. No analgesia was noted. The solution used in this case was not fresh, and had been boiled by mistake for thirty minutes.

M. L., aged 48, had sarcoma of the uterus. We injected 1.5 c.c. of a 1 per cent. solution of cocain, after having withdrawn 1 c.c. of liquid. Analgesia of the right leg was noted after eighteen, and of both legs after twenty-five minutes. There was no analgesia of the clitoris after thirty minutes, when vaginal hysterectomy was performed. Vaginal incision with the Paquelin cautery was painless. Traction on the broad ligaments caused very slight pain. Section of th broad ligaments and extraction of the left ovary proved painless. The pressure of the clamp was not noticed by the patient during or after the operation. The latter lasted twenty minutes. The analgesia had then exended as high as the clavicles; the patient neither felt the puncture for hypodermoclysis nor was discommoded in the least by the consequent distension; she complained of the noise of the instruments. There were no unpleasant after-effects. Analgesia lasted one hour and ten minutes, and the patient had her usual liquid diet during the same afternoon. The clamps were removed after forty-eight hours.

M. N., aged 40, suffered with a tuberculous knee. We injected 1.5 c.c. of a 1 per cent. solution of cocain, after having withdrawn 3 c.c. of fluid. Analgesia was noted in both legs after twelve minutes. After the usual transverse incision for resection of the knee, and a most thorough exploration of the bones and soft parts, a condition was revealed which contraindicated resection. Consequently, the wound was closed, and the patient informed of the necessity of an amputation. No pain was noted at any time during the operation, which lasted fifteen minutes. The analgesia continued one hour and five minutes. The patient complained of slight nausea shortly afterward, but this ceased rapidly. Death occurred two and one-half months later, from general tuberculosis. Necropsy showed normal cord and meninges in the lumbar region.

M.M., aged 26, had inguinal hernia, and was injected with 2 c.c. of a .5 per cent. solution of cocain. Five minutes later analgesia was noted in both legs. The operation—a modified Bassini—was begun one minute later. The skin incision was painless, but some discomfort was noted during the incision of the fascia of the oblique, and the dissection of the sac from the cord. The patient was rendered nervous by the noise of the instruments. The resection of 15 cm. of omentum was painless. The upper part of the deep layer of sutures caused some pain, but the lower part proved almost painless. The suturing of the skin was not altogether painless. No troublesome after-effects occurred. In this case the cocain was diluted with the intention of increasing its diffusion; the solution was, however, too weak.

M. L. had necrosis of tibia, and we injected 1.5 c.c. of a 1 per cent. solution of cocain after having withdrawn 1.5 c.c. cerebrospinal fluid. Analgesia was [illegible] after [illegible] minutes. Exploration and curetting began [illegible] in was experienced, and no after-effects. This patient had collapsed under chloroform and also under ether anesthesia on former occasions.

We have endeavored to apply subarachnoid injections of cocain to obstetrics but we reserve this part of our work for further study. In the study of cocain we found that its local action was in an inverse proportion to its degree of dilution, and that the diffusibility increased in proportion to the amount of the liquid injected. Our experience teaches us that the disagreeable after-effects of subarachnoid injections of cocain are, in part, due to the sudden increase of pressure, and may be avoided by the preliminary extraction of a small amount of fluid, and by making the injection slowly. The amount of cocain is also a factor of importance. With more than 1.50 c.c. of 1 per cent. solution, or more than 1 c.c. of a 1.5 per cent. solution of cocain, we generally noted more nausea, headache and weakness. Toxic symptoms occur in the subarachnoid method in very much the same manner as in the intradermic method of cocainization. In the search for substances less toxic than cocain, we considered eucain and nirvanin. The former, in animals, seemed to differ but little from cocain. Nirvanin, even in a 5 per cent. solution, used subcutaneously, proved less toxic than cocain, but only slightly diffusible. The analgesia induced is less pronounced and disappears more rapidly than that caused by cocain. Schleich's mixture is valueless for subarachnoid use.

CONCLUSIONS.

1. To the already known practical routes leading to the subarachnoid space, we propose to add the "low cervical"—in the sixth cervical space—which we find both easy and safe.

2. The cerebrospinal fluid possesses none of the properties of lymph.

3. Contrary to the classic opinion, the cerebral perivascular lymphatic sheaths do not empty into the subarachnoid space. (Sicard.)

4. Liquids injected by lumbar puncture diffuse rapidly toward the different cavities of the brain, and subsequently reach the cortex.

5. The difference in osmotic currents in the cerebrospinal fluid—presence of exosmosis and absence of endosmosis—in addition to the protection afforded by the perivascular lymphatic sheaths, explains the rarity of infection of the cerebrospinal fluid in the course of generalized blood infections and also the gravity of primary infections of the cerebrospinal fluid. (Sicard.)

6. Direct intramedullary medication is feasible and deserving of further trial.

7. Subarachnoid injections of cocain are devoid of danger if made with certain precautions. The solution should be freshly prepared and injected slowly at a temperature of 37 C. and never in a greater quantity than 3 c.c.

8. The extent and duration of the analgesia thus induced is generally in direct proportion to the amount of drug injected. Analgesia is noted in some cases as early as five minutes, after the injection, and in others, for unknown reasons, as late as thirty-five minutes. Its duration is sufficient for the performance of all operations on the lower limbs and pelvis, and may be sufficient to be of service in obstetrics.

9. The disagreeable effects—headache and vomiting—sometimes noted after these injections, are partly due to the sudden increase of pressure in the subarachnoid space—too rapid diffusion toward the brain—and principally to the amount of cocain used. These post-operative symptoms are never alarming or lasting. They recall the effects of intradermic injections of cocain, and never resemble in severity the symptoms so frequently observed during and after chloroform or ether anesthesia.

10. One c.c. of a 1 per cent. solution of cocain injected slowly is generally sufficient for all practical purposes, and is not followed by untoward symptoms.

11. For obvious reasons, it is a good plan to withdraw a small amount of cerebrospinal fluid prior to making an injection.

12. To the careful surgeon, who aims to gradually divorce himself from the dangers of general anesthesia, and the limitations of superficial analgesia, spinal analgesia, may, under certain exceptional conditions, prove of signal service, and it behooves us to herald abroad the fact that this progressive step was made by a modest American surgeon—J. Leonard Corning.

THE SURGERY OF BILIARY CALCULI.*

WILLIAM D. HAGGARD, Jr., M.D.

Professor of Gynecology and Abdominal Surgery, University of the South, (Sewanee); Associate Professor of Gynecology, Medical Department University of Tennessee; Gynecologist to the Nashville City Hospital; Fellow of the Southern Surgical and Gynecological Association; Member of the Alumni Association of the Woman's Hospital of New York, etc.
NASHVILLE, TENN.

I shall restrict my remarks to the surgical aspect of biliary calculi, as a consideration of the causation, frequency, symptoms of the various phases, their diagnosis and discriminating diagnoses, widespread complications, prognosis and medical treatment, so-called, would lead me far beyond the limits of a thesis of this character.

---

*Read before the Eleventh Annual Meeting of the Southern Surgical and Gynecological Association, New Orleans, La., Dec. 5-8, 1899.

It may not be amiss, however, in describing the surgery of the gall-tracts, to allude to the very great frequency of gall-stones, as almost all organic diseases of the biliary reservoir and ducts are directly or indirectly dependent upon them. The frequent findings of unsuspected gall-stones at autopsies is not a valid contraindication to operation in cases which, from certain complications, menace well-being and perhaps life.

The causation has been held to be the stagnation of bile with an altered condition of the epithelium, forming both the nucleus and media for their development and resulting from various mechanical, diathetic and inflammatory conditions. It is to the latter, perhaps, that we may look for a simplification of the various existing etiologic hypotheses. The element of infection of the biliary ways in the production of gall-stone is an undetermined quantity. It may be stated that Mignot produced cholelithiasis by the injection of bacteria into the gall-bladder.

The supreme symptom is pain; when this occurs in the right hypochondrium it is always significant. It may vary from slight discomfort to the agony of a biliary colic, which is equaled only by the parturient effort. It is important to discriminate between the intermittent and paroxysmal pain in biliary concretions, from the continuous pain in the inflammatory infective and suppurative conditions of the biliary passages.

In connection with the diagnosis I wish strongly to emphasize that jaundice is not an essential sign of gall-stones and the practice of waiting for icterus as a confirmatory evidence of their existence is illogical and positively hurtful. Jaundice is a symptom common to the whole biliary tract, whether from inflammation, retention or obstruction. While in the latter, jaundice is inevitable, it is also commonly present from extension in simple catarrhal duodenitis. Hunter McGuire[1] says: "According to my observation, at least one-half of the cases of gall-stones are never attended by jaundice and at least one-half the cases of persistent jaundice are not due to gall-stones."

I should like to speak also of the cholangeal inflammations and also of the suppurative and infective conditions and their differentiation from lithiasis, but these can not be treated in the scope of this paper, except to call attention to them as being frequent concomitants and resultants of gall-stones; and to urge the early removal of troublesome cholelithiasis in the light of its inflammatory and ulcerative possibilities as well as its undoubted causal relationship to malignant disease.

The relatively small number of operations compared with the undisputed frequency of the disease, indicates that it is either overlooked or fails to give rise to serious trouble, or that the symptoms are mistaken for those of other disorders. The actual mortality is not known, as it is often a vague and undetermined malady and, when grave, is frequently considered only in the light of the complicating conditions. In regard to the surgical mortality, however, sufficient evidence has accumulated to allow us to draw convincing conclusions.

In the past eight years Kehr[2] has done 307 operations for cholelithiasis—255 women and 52 men. The total mortality was 11.7 per cent. Excluding deaths due to the pathologic condition, as hopeless carcinoma, advanced suppurative condition, etc., the actual mortality was 3.8 per cent.

Mayo Robson[3] gives the following indications for surgical operations on the gall-bladder or biliary passages: 1. Recurring attacks of biliary colic, with or without jaundice, and whether the gall-bladder is enlarged or not. 2. Enlargement of the gall-bladder, whether there be pain or not. 3. Persistent jaundice which was preceded or accompanied by pain in the region of the gall-bladder, with or without paroxysms resembling ague. 4. Empyema of gall-bladder, or peritonitis in gall-bladder region. 5. Abscess in region of gall-bladder. 6. Rupture, fistula, or wounds of gall-bladder.

The lessened danger of hernia in this region makes amplitude of exposure the sole consideration.

In tumefaction, linear incision over the prominence is all that is required. For exploration, a small vertical incision through skin, fascia, and peritoneum can be made at the outer border of the right rectus, beginning at the top of the tenth costal cartilage. This can be prolonged downward to any needed length and joined by another incision at right angles to it and across the rectus muscle, to give a liberal exposure of the subhepatic space. (Abbe.)

Somewhat the reverse of this triangular incision is proposed by Czerny, who begins his incision in the median line and prolongs it transversely to the right at the level of the umbilicus.

The oblique or transverse incision of Courvoisier, parallel with, and one-half inch below the lower border of the ribs, is capable of easy extension and gives adequate room for manipulation.

Bevan employs an S-shaped incision, for which most liberal exposure is claimed.

Of the operations on the gall-bladder, I shall discuss cholecystotomy, cholecystendesis, modified cholecystotomy without suture and cholecystectomy.

CHOLECYSTOTOMY.

Incision of the gall-bladder and suturing the cut edges to the parietal incision, with drainage, like many important life-saving surgical procedures, is of American origin, having been first performed by Dr. Bobbs, of Indiana, in 1867. It is the simplest of the gall-bladder operations, is applicable to the majority of cases, mortality is practically nil in cases without In 115 cases, Mayo Robson[4] lost 5, 3 of which w plicated with cancer and 2 with infective cho and jaundice. Excluding these there were no 100 uncomplicated cases.

Technique.—The usual vertical incision th downward from the tip of the tenth costal cartil ally exposes the gall-bladder. If adherent, as th of previous severe or existing inflammation, it sh freed from neighboring viscera. The next an important technical step is the complete and surrounding of the gall-bladder with sterile disposed as to entirely wall off the field of from the peritoneal cavity. It is convenient duce two stout silk ligatures into the fundus guy-lines. The contents may then be aspirated gall-bladder incised for exploration with the Calculi may be removed with the finger, forceps After all the discernible stones have been extra operator should make a careful palpation of the If any stones are detected they should be removed appropriate maneuver. The edges of the gall bl incision are then sutured to the peritoneal and f margins of the wound by chromicized catgut. A experienced, and no after-effects. This patient had collapsed under chloroform and also under ether anesthesia on former occasions.

We have endeavored to apply subarachnoid injections of cocain to obstetrics but we reserve this part of our work for further study. In the study of cocain we found that its local action was in an inverse proportion to its degree of dilution, and that the diffusibility increased in proportion to the amount of the liquid injected. Our experience teaches us that the disagreeable after-effects of subarachnoid injections of cocain are, in part, due to the sudden increase of pressure, and may be avoided by the preliminary extraction of a small amount of fluid, and by making the injection slowly. The amount of cocain is also a factor of importance. With more than 1.50 c.c of 1 per cent. solution, or more than 1 c.c. of a 1.5 per cent. solution of cocain, we generally noted more nausea, headache and weakness. Toxic symptoms occur in the subarachnoid method in very much the same manner as in the intradermic method of cocainization. In the search for substances less toxic than cocain, we considered eucain and nirvanin. The former, in animals, seemed to differ but little from cocain. Nirvanin, even in a 5 per cent. solution, used subcutaneously, proved less toxic than cocain, but only slightly diffusible. The analgesia induced is less pronounced and disappears more rapidly than that caused by cocain. Schleich's mixture is valueless for subarachnoid use.

CONCLUSIONS.

1. To the already known practical routes leading to the subarachnoid space, we propose to add the "low cervical"—in the sixth cervical space—which we find both easy and safe.

2. The cerebrospinal fluid possesses none of the properties of lymph.

3. Contrary to the classic opinion, the cerebral perivascular lymphatic sheaths do not empty into the subarachnoid space. (Sicard.)

4. Liquids injected by lumbar puncture diffuse rapidly toward the different cavities of the brain, and subsequently reach the cortex.

5. THE SURGERY OF BILIARY CALCULI.*

WILLIAM D. HAGGARD, Jr., M.D.

Professor of Gynecology and Abdominal Surgery, University of the South, (Sewanee); Associate Professor of Gynecology, Medical Department University of Tennessee; Gynecologist to the Nashville City Hospital; Fellow of the Southern Surgical and Gynecological Association; Member of the Alumni Association of the Woman's Hospital of New York, etc.

NASHVILLE, TENN.

I shall restrict my remarks to the surgical aspect of biliary calculi, as a consideration of the causation, frequency, symptoms of the various phases, their diagnosis and discriminating diagnoses, widespread complications, prognosis and medical treatment, so-called, would lead me far beyond the limits of a thesis of this character.

---

*Read before the Eleventh Annual Meeting of the Southern Surgical and Gynecological Association, New Orleans, La., Dec. 5-8, 1899.

It may not be amiss, however, in describing the surgery of the gall-tracts, to allude to the very great frequency of gall-stones, as almost all organic diseases of the biliary reservoir and ducts are directly or indirectly dependent upon them. The frequent findings of unsuspected gall-stones at autopsies is not a valid contraindication to operation in cases which, from certain complications, menace well-being and perhaps life.

The causation has been held to be the stagnation of bile with an altered condition of the epithelium, forming both the nucleus and media for their development and resulting from various mechanical, diathetic and inflammatory conditions. It is to the latter, perhaps, that we may look for a simplification of the various existing etiologic hypotheses. The element of infection of the biliary ways in the production of gall-stone is an undetermined quantity. It may be stated that Mignot produced cholelithiasis by the injection of bacteria into the gall-bladder.

The supreme symptom is pain; when this occurs in the right hypochondrium it is always significant. It may vary from slight discomfort to the agony of a biliary colic, which is equaled only by the parturient effort. It is important to discriminate between the intermittent and paroxysmal pain in biliary concretions, from the continuous pain in the inflammatory infective and suppurative conditions of the biliary passages.

In connection with the diagnosis I wish strongly to emphasize that jaundice is not an essential sign of gall-stones and the practice of waiting for icterus as a confirmatory evidence of their existence is illogical and positively hurtful. Jaundice is a symptom common to the whole biliary tract, whether from inflammation, retention or obstruction. While in the latter, jaundice is inevitable, it is also commonly present from extension in simple catarrhal duodenitis. Hunter McGuire[1] says: "According to my observation, at least one-half of the cases of gall-stones are never attended by jaundice and at least one-half the cases of persistent jaundice are not due to gall-stones."

I should like to speak also of the cholangeal inflammations and also of the suppurative and infective conditions and their differentiation from lithiasis, but these can not be treated in the scope of this paper, except to call attention to them as being frequent concomitants and resultants of gall-stones; and to urge the early removal of troublesome cholelithiasis in the light of its inflammatory and ulcerative possibilities as well as its undoubted causal relationship to malignant disease.

The relatively small number of operations compared with the undisputed frequency of the disease, indicates that it is either overlooked or fails to give rise to serious trouble, or that the symptoms are mistaken for those of other disorders. The actual mortality is not known, as it is often a vague and undetermined malady and, when grave, is frequently considered only in the light of the complicating conditions. In regard to the surgical mortality, however, sufficient evidence has accumulated to allow us to draw convincing conclusions.

In the past eight years Kehr[2] has done 307 operations for cholelithiasis—255 women and 52 men. The total mortality was 11.7 per cent. Excluding deaths due to the pathologic condition, as hopeless carcinoma, advanced suppurative condition, etc., the actual mortality was 3.8 per cent.

Mayo Robson[3] gives the following indications for surgical operations on the gall-bladder or biliary passages: 1. Recurring attacks of biliary colic, with or without jaundice, and whether the gall-bladder is enlarged or not. 2. Enlargement of the gall-bladder, whether there be pain or not. 3. Persistent jaundice which was preceded or accompanied by pain in the region of the gall-bladder, with or without paroxysms resembling ague. 4. Empyema of gall-bladder, or peritonitis in gall-bladder region. 5. Abscess in region of gall-bladder. 6. Rupture, fistula, or wounds of gall-bladder.

The lessened danger of hernia in this region makes amplitude of exposure the sole consideration.

In tumefaction, linear incision over the prominence is all that is required. For exploration, a small vertical incision through skin, fascia, and peritoneum can be made at the outer border of the right rectus, beginning at the top of the tenth costal cartilage. This can be prolonged downward to any needed length and joined by another incision at right angles to it and across the rectus muscle, to give a liberal exposure of the subhepatic space. (Abbe.)

Somewhat the reverse of this triangular incision is proposed by Czerny, who begins his incision in the median line and prolongs it transversely to the right at the level of the umbilicus.

The oblique or transverse incision of Courvoisier, parallel with, and one-half inch below the lower border of the ribs, is capable of easy extension and gives adequate room for manipulation.

Bevan employs an S-shaped incision, for which most liberal exposure is claimed.

Of the operations on the gall-bladder, I shall discuss cholecystotomy, cholecystendesis, modified cholecystotomy without suture and cholecystectomy.

CHOLECYSTOTOMY.

Incision of the gall-bladder and suturing the cut edges to the parietal incision, with drainage, like many important life-saving surgical procedures, is of American origin, having been first performed by Dr. Bobbs, of Indiana, in 1867. It is the simplest of the gall-bladder operations, is applicable to the majority of cases, and the mortality is practically nil in cases without jaundice. In 115 cases, Mayo Robson[4] lost 5, 3 of which were complicated with cancer and 2 with infective cholangitis and jaundice. Excluding these there were no deaths in 100 uncomplicated cases.

Technique.—The usual vertical incision three inches downward from the tip of the tenth costal cartilage usually exposes the gall-bladder. If adherent, as the result of previous severe or existing inflammation, it should be freed from neighboring viscera. The next and most important technical step is the complete and careful surrounding of the gall-bladder with sterile gauze so disposed as to entirely wall off the field of operation from the peritoneal cavity. It is convenient to introduce two stout silk ligatures into the fundus to act as guy-lines. The contents may then be aspirated and the gall-bladder incised for exploration with the finger. Calculi may be removed with the finger, forceps or scoop. After all the discernible stones have been extracted, the operator should make a careful palpation of the ducts. If any stones are detected they should be removed by the appropriate maneuver. The edges of the gall-bladder incision are then sutured to the peritoneal and fascial margins of the wound by chromicized catgut. A non-perforated rubber drainage-tube is introduced and the parietal wound partly closed by sutures. Copious dressings should receive the bile, or it may be siphoned into a bottle by rubber tubing. At the end of ten days the bile may be dammed up by a pad, and the opening usually closes in three or four weeks: If a sinus persist, there is usually a stone imbedded somewhere in the biliary tract, but many stones, overlooked or left, work out later.

Fistulæ resulted in 50 per cent. of Robson's cases where the gall-bladder was sutured to the skin, but in only 7 out of 160 cholecystotomies where it was sewn to the aponeurosis, all of which were ultimately cured by appropriate means.

The earlier operations were always, and a certain number are now, done in two stages. It avoids the risk of peritonitis, especially in the infected cases. It is much simpler and should commend itself to the inexperienced operator. To the expert it is less often required. Kehr employed it only 3 times in 100 cases. In acute cholecystitis, where the gall-bladder is small, deeply seated and can not be satisfactorily sutured to the incision, Riedel advocates the two-stage method, by allowing adhesions to form about a gauze tamponade, before incising the gall-bladder. The chief objection to the operation in two stages is that an impacted stone in one of the ducts could not be removed and might require a second operation.

CHOLECYSTENDESIS.

Immediate suturing of the gall-bladder after incision and extraction of the stone was first suggested by Langenbuch.[5] It is requisite that the bile-channels be open. It is the ideal operation in that it leaves no biliary fistula, but it presents the danger of peritonitis from leakage, prevents needful drainage of the inflamed tracts and walls off the cholecystitis and also cuts off the escape of any remaining concretions. It should be reserved for early cases, with slight inflammatory changes. Two rows of Lembert sutures are required.

MODIFIED CHOLECYSTOTOMY.

A modification of cholecystotomy, by Poppert, of Giessen, has recently been described by Coley,[9] as follows:

> The first steps of the procedure recommended by Poppert are the usual ones, namely, the incision of the gall-bladder and removal of the calculi; then, however, instead of directly suturing the bladder to the abdominal wound, he establishes between the two a narrow drainage by means of a thick and long drain, which is fixed by a suture in the lowest point of the incision in the bladder, and the lips of the wound are drawn as tightly as possible around it. The other end of the drain is sutured to the abdominal wound and is surrounded by a wick of iodoform gauze, which at the same time serves as a dressing for the bladder incision. The bile flows out through this tube of caoutchouc. In ten to fifteen days the obliteration of the bladder around the drain ceases, as is shown by the fact that the bile impregnates the wick and soils the dressing. At this time, however, the adhesions having been formed around the drain, there is no longer any danger of the bile escaping into the peritoneum. Then the iodoform wick can be taken out, and at the end of from three to four weeks the drain is removed. The fistula closes rapidly.
>
> The author has practiced this mode of drainage in forty-seven cases of simple cystostomy, and in ten cases of cystotomy combined with cysticotomy or choledochotomy. He has never had a failure, and claims the following advantages for his method:
>
> 1. It is extremely simple, and may be practiced in all cases where the bladder is distended or contracted. The method can be employed even in friable bladders—which heretofore have been considered as unfit for operation—and even in worse conditions.
>
> 2. It does not cause the formation of tight adhesions between the bladder and the abdominal wall and does not cause any painful contractions of the bladder and great biliary canals when the bladder and liver resume their places.
>
> 3. It affords protection against peritonitis, for as the bile flows out of the cystic wound it is absorbed by the tampons. The tamponade becomes particularly valuable when it is necessary to open an abscess situated above the bladder.

This has also been done by many American surgeons, and cases were reported by Longyear, of Detroit, and Hall, of Cincinnati, in 1893.[15]

CHOLECYSTECTOMY.

Excision of the gall-bladder was first performed by Langenbuch in 1882. It is regarded by Thiriar as the least dangerous of the operations on the gall-bladder. Its indications may be summarized: 1. As a secondary operation for persistent mucous fistula, as a result of insuperable obstruction of the cystic duct. (Robson.) 2. When the gall-bladder is contracted and can with difficulty be brought into the incision, extirpation can be practiced if the common duct is undoubtedly free. 3. Where the friability of the organ from inflammatory disorganization precludes other indicated procedures. 4. Malignancy, gangrene and ulceration.

The operation is anatomically exceedingly simple, requiring only blunt dissection of the attachment to the liver and ligation of the cystic duct, followed, or not, by drainage. The portion attached to the liver in a necrotic gall-bladder was left by Gaston, and the remainder trimmed away after ligation. Dr. Clinton Cushing[16] assumes that as the gall-bladder is absent in certain animals, such as the horse, the deer, and the elephant, it is probably, like the appendix, a vestigeal organ, and can be removed without detriment to the physiology of the economy, and that, being a cul-de-sac, a serious disease having once occurred was likely to return. He advocated excision in all cases of operation for gall-stones, save obstruction, to prevent reaccumulation or renewal of inflammation. He reported six cases, all followed by recovery.

On the other hand, Rose[8] considers the function and retention of the gall-bladder very important and advocates exploration of the ducts by incision at its base, and clearing the tract of stones by that avenue. He found that disablement of the gall-bladder caused compensatory dilatation of the other ducts, and that the continuance of such disablement or cholecystectomy would lead to new secondary lithiasis in the branches of the hepatic duct.

The surgery of the gall-bladder is almost perfected, but the management of calculi in the ducts by the various methods is as yet unsettled. I shall discuss the following operations on the ducts: Cholelithotrity, cysticotomy, choledochotomy and choledochostomy.

CHOLELITHOTRITY.

Cholelithotrity, or crushing the calculus in the duct, has been said to be preferable to incision. This is accomplished by: *a*, finger pressure; *b*, pressure by padded forceps; *c*, needling. The first is the least objectionable and Robson reports thirty cases with one death. Needling or breaking the stone into fragments was suggested by Mr. Thornton; crushing was suggested by Mr. Tait, and is the least of his wonderful work in this field. Both crushing and pressure by padded forceps have some of the dangers of incision and may present others, such as leaving debris as nuclei for further concretions. They were practiced before the surgery of the ducts had reached its present stage of advancement, and are infrequently employed at this time.

CYSTICOTOMY.

Cysticotomy is the operation for incision of the cystic duct, and extraction of stone with or without suturing. The cystic and hepatic ducts and the upper part of the ductus communis choledochus can be reached by an incision through the anterior layer of the gastro-hepatic omentum, the liver and gall-bladder being drawn strongly upward. Cysticotomy is rarely required and only when a stone is so firmly impacted that attempts at dislodgment by manipulation and pressure fail. Drainage should be established with or without suture. Kehr operated on the cystic duct 23 times without a death.

CHOLEDOCHOTOMY.

Courvoisier estimated that 4 per cent. of gall-stones were located in the common duct, but Robson says from a surgical standpoint, 20 per cent. is not too high. Clayton Parkhill[13] says that stones were removed from the common duct 200 years ago. Courvoisier deliberately planned and performed the operation of choledochotomy in 1890, but Marcy, of Boston, removed a stone from the cystic duct the year before. The lower part of the choledochus may be reached by cutting through the peritoneum at the right of the first or second portion of the duodenum toward the median line. All manipulations, and especially suturing of the common duct, are rendered far more easy, as urged by Deaver,[14] when the finger is inserted in the foramen of Winslow, thus elevating the duct in the border of the gastro-hepatic omentum. It can be accurately palpated and an impacted stone can sometimes be pushed into the duodenum or back into the gall-bladder. The cystic and also a portion of the hepatic duct can be palpated. When the stone is located, linear incision of the duct can be made with the finger behind it, great care being exercised to prevent injuring the portal vein. In all operations on the duct, a sandbag under the back brings it more easily within reach. The feet should be lowered to allow the colon to gravitate downward, the liver being held up by large retractors. Gauze pads should be snugly packed about the field of operation. Adhesions, which usually exist, should be very delicately severed. If suturing is contemplated it should be done in layers, fine catgut uniting the muscularis, and Lembert sutures of silk, the peritoneum. Halsted[6] has described minute hammers for elevating the duct and putting it on a stretch to facilitate suturng. It is difficult to prevent leakage by any method, and it is best to drain. If it is inexpedient to suture, the entire efficacy of drainage with gauze has been abundantly proved and its employment ardently insisted upon, by W. E. B. Davis, who has made so many important contributions to the surgery of the gall-ducts. The importance of this suggestion is well illustrated by a recent report. Quénu[7] collected 95 cases of suture of the ducts with a mortality of 35.5 per cent., while the mortality in the cases without suture was only 18 per cent. In these were included 6 personal cases. In 2, sutures were used; both died. In 2 others biliary intoxication appeared; the sutures were cut and the patient recovered. The other two were not sutured and recovered.

Fenger[9] also believes that the common duct should not be sutured as a rule, and never without drainage, from the site of incision in the duct, and particularly drainage of the gall-bladder to prevent biliary intoxication. McBurney[15] has suggested that the anterior wall of the duodenum be opened at the junction of the first and second portion, and the common duct approached through the intestine. This obviates the difficult exposure and manipulation of the duct by the usual method, gives easy access to the stone by dilatation and slight incision of the duodenal opening of the duct, allows free probing for other stones, greater safety in suture of the duodenum, and more rapid recovery. He has performed the operation six times. Parkhill,[13] of Denver, has made a Murphy-button anastomosis between the common duct and duodenum with success, and Robson reports two similar anastomoses, by suture, with recovery.

Fenger collected 44 cases of choledochotomy in 1896, with a mortality of 18 per cent. He has operated on 7 cases, with 1 death, a mortality of 14.3 per cent. Kehr has had 7 operations with a mortality of 11.7 per cent.; Peterson[11] 20 cases, with 4 deaths, a mortality of 20 per cent.; and Robson 49 cases, with a mortality of 6.1 per cent., jaundice and suppurative cholangitis being present in all of his fatal cases.

CHOLEDOCHOSTOMY.

Choledochostomy, or attaching the duct to the incision in the anterior abdominal wall is rarely necessary, always difficult and sometimes quite impossible.

CHOLECYSTENTEROSTOMY.

Cholecystenterostomy, or making a permanent fistula between the gall-bladder and intestinal canal, by suture or mechanical appliance, is indicated to short-circuit the bile in: 1. Irremediable obstruction of the common duct from *a*, stone; *b*, adhesion; *c*, angulation; *d*, chronic catarrhal cholangitis producing jaundice. 2. Persistent biliary fistula. 3. Obstructive jaundice from pressure of cancer.

The first cholecystenterostomy was performed by Winiwarter, of Liège, in 1880, who sewed the gall-bladder to the colon and attached both to the abdominal wall. After union had occurred, he opened the approximated surfaces and sewed the cut margins together, as we do in making lateral anastomosis by suture. After five attempts he succeeded. But it was the genius of a southern surgeon, Dr. J. McFadden Gaston, that gave to humanity the operation of duodeno-cholecystenterostomy,[17] in 1882. This was first performed on the human subject by Terrier, in 1889. However, it has been a safe and generally applicable procedure only for the last dozen years. The introduction of that most ingenious surgical device of the age, the Murphy button, has given the operation a much wider scope by the simplicity of the device and the rapidity with which it can be applied. Murphy collected thirty-eight cases without a death, some years ago, all that had been reported up to that time. Many of these operations have been done since with uniformly good results.

There is a certain class of cases where, owing to the contracted condition of the gall-bladder, or fixity of the duodenum in the depths of the loin as a result of inflammatory changes, the viscera can not be made to approximate each other and in that event the colon may be substituted. While it should be our aim to restore parts to as nearly a normal and physiologic condition as possible, still where it is inconvenient and impossible to switch the bile into the duodenum, we may utilize the colon, as has been frequently done, without detriment to the economy in the supposed necessary presence of bile in the small intestine. This possibility was abundantly proved by the elaborate and carefully conducted experiments by Robson[18] on a case of biliary fistula, which he epitomized in the following conclusions:

1. The bile is probably chiefly excrementitious, and like the urine, is constantly being formed and cast out.

2. Though the bile probably assists in the absorption of fats, its presence in the intestine is not necessary for the digestion of such an amount of fat as is capable of supporting life and keeping up nutrition.

3. Increase in body-weight and good health are quite compatible with the entire absence of bile from the intestines.

4. The antiseptic properties of the bile are unimportant. 5. Whatever little antiseptic quality bile may have is probably derived from its admixture with the gall-bladder fluid.

6. The supposed stimulating effect of the bile on the intestinal walls is not necessary for a regular action of the bowels.

COLOCHOLECYSTOSTOMY.

I beg leave to briefly report the following case of colocholecystostomy for chronic catarrhal cholangitis with gallstones:

B. J. G., male, aged 27, had a severe attack of biliary colic attended with tenderness and jaundice in February, 1897. He had had several light attacks of hepatic colic some weeks before, and he had been in Johns Hopkins Hospital, Baltimore, awaiting operation, but improved, and so it was deferred. He was operated on after the severe attack in 1897, by Dr. J. F. W. Ross, of Toronto. A number of stones were removed, a fistula made and a drainage-tube kept in for two weeks. The fistula remained open until June, 1897, when Dr. Ross closed it by suture, and the patient, who had been in bed the whole of the four months, was up in a week. In November, 1897, he again had a number of attacks of colic and jaundice, which kept up *intermittently* until March, 1898, when Dr. Louis McLane Tiffany, of Baltimore, opened the gall-bladder. As he found no stones, he closed by immediate suture, fixed it to the abdominal wall, and closed the incision throughout.

In June of the same year, while still in the hospital, the patient was again seized with attacks of colic and transient jaundice, which, in the absence of Dr. Tiffany, induced his assistant, Dr. I. R. Trimble, to again open the gall-bladder for exploration. He wrote me that he found no stones, but thought he had succeeded in passing a rubber catheter through the cystic duct and thence into the duodenum. The gall-bladder was sutured and attached to the abdominal incision, which was closed by buried and superficial silkworm gut sutures.

On July 3, he received a blow on the head, which resulted in a fracture of the skull, which was elevated by Dr. Robert Pillow, of Columbia, Tenn.

In August, 1899, fourteen months after the third gall-bladder operation the pain and colic returned and was rather frequent and more severe than ever before. On October 1, he had an attack that lasted four days, and could obtain no relief. He came to see me in Nashville and, while there, had one of the most severe attacks of biliary colic I have ever seen. I gave him 2¾ gr. of morphin, hypodermically, in less than three hours without any appreciable effect on the pain. He was not accustomed to taking morphin, and after the operation 1/8 gr. had a very satisfactory and complete effect.

On Oct. 12, 1899, in the presence of jaundice which had existed fitfully for two months, I made an exploratory operation through the old scar parallel with the ribs. As the gall-bladder was attached to the parietes, it was opened, and a black, tarry fluid was found therein and one large gall-stone, perfectly black and somewhat larger than a cherry-stone, together with some smaller crystal-like stones. An effort was made to catheterize the ducts, which it was reported had been done before without success. The gall-bladder was irrigated and temporarily packed with gauze. It was then dissected from the parietes below and a careful palpation of the ducts made, but no other stones could be detected. The adhesions were very considerable as the result of so many previous operations and such long-continued inflammatory trouble, and the gall-bladder was much contracted. I did not wish to content myself simply with the removal of the two small stones, nor yet did I desire to close it up again or give him another biliary fistula, both of which had failed to give permanent relief. Kelly, Senn and Murphy had all advised a cholecystectomy, but after I found no calculous obstruction to account for the recent colic and existing jaundice, I concluded that it must be a chronic catarrhal cholangitis with intermittent inflammatory obstruction. I thereupon deemed it unwise to do a cholecystectomy, and decided to make a cholecystenterostomy. The duodenum, however, was so matted with adhesions and the gall-bladder was contracted to such an extent that I did not think I could make the anastomosis with safety. I, therefore, utilized the hepatic flexure and made a Murphy button anastomosis with gauze drainage. There was no untoward symptom. A little bile came out after the removal of the gauze, on the third day, but none thereafter, and the drainage tract closed quickly. The jaundice faded, urine cleared up and he had two normal bowel movements a day, whereas, he had previously been obliged to take purgatives daily. He went home at the end of two weeks, with a clear complexion and a gain in weight; has had no trouble since, but the button has not passed.

McGuire reports a button retained over a year after cholecystenterostomy, but Treves has never known one to remain in the gall-bladder.

Note.—I have had a communication from Dr. Ross since this paper was read, referring me to a report of the first operation performed by Dr. Ross, upon this patient; the specimens were illustrated in the International Clinics for October, 1897, Vol. iii, 7th Series. About 3000 gall-stones were removed which were *denominated by Ross and also by Frerichs, "biliary gravel."*

A CASE OF PERFORATING GASTRIC ULCER.*

ALLEN JONES, M.D.

Adjunct Professor of Principles and Practice of Medicine, University of Buffalo.

BUFFALO, N. Y.

For the following case I am indebted to Dr. A. B. Beiver, of Ridgway, Pa., who kindly referred the patient to me Sept. 20, 1899.

The patient was a man, by nativity a Swede, aged 57 years, by occupation a tanner. He said that his father died at the age of 90 and his mother at the age of 45—cause unknown. He had two brothers and two sisters, all of whom were in good health. The man had been suffering for five years from recurring attacks of gastric pain and vomiting. After stopping work and abstaining from all but small quantities of predigested milk and other liquid foods for a few weeks, his vomiting ceased, and he rapidly gained strength and returned to work. This happened several times and each succeeding attack was more severe than the former until finally, before I saw him, he had not been at work for four months. Owing to circumstances which prevented me being in my office when the patient first called, Drs. Stockton and Woehert very kindly examined him for me. He complained of weakness, loss of flesh, poor appetite, pain in the epigastrium, eructations and vomiting. He was constipated most of the time, but occasionally had attacks of diarrhea. His skin was sodden; his urine amounted to 864 c.c. in 24 hours, and the urea to 16.41 grams; there was a trace of albumin, but no sugar and no indican; the acidity was normal and the microscopic examination negative. The thoracic organs were normal, though the pulse was weak and the capillary circulation poor.

---

*Read before the Fourth District Branch of the N. Y. Medical Association, Buffalo, May 8, 1900.

The first examination of the stomach showed moderate gastric stasis but no marked stagnation. The total acidity was 56; the free hydrochloric acid registered .12 per cent.; no lactic acid was found. On October 5, I examined the stomach before breakfast and found a lot of the food eaten the night before—the odor of which was not offensive though the mass was somewhat yeasty. Free hydrochloric acid was present; lactic acid was absent; butyric and acetic acids were present; hemialbumoses and peptone were present in large quantities; rennet ferment was active; starches were not digested. Microscopically, a goodly number of large long bacilli and strings of cocci were found but no Oppler-Boas bacilli were discovered. Subsequent examinations revealed similar motor, chemical and microscopic conditions, and as there was never at any time epigastric tumor to be felt, a provisional diagnosis of benign stenosis was made. There was no history of hematemesis nor was any blood found in the gastric contents. Diet, gastric sedatives and local treatment proving of no avail, operation was advised. On October 19, Dr. Park made a median epigastric incision and found the lesser curvature and pylorus attached to the liver by recent adhesions which were separated and revealed a clean chronic perforating ulcer of the superior anterior surface, very near the pylorus. The perforation was large enough to admit a lead pencil and the chronic nature of the ulcer was apparent by the formation of a new epithelial surface over almost its entire depth and by the large amount of thickening in and about its margins. The pylorus was amply patulous. Pylorectomy was performed and the patient succumbed a few days later owing, doubtless, to the fact that he was seriously weakened and reduced before the operation and was much past middle age. Pyloric stenosis probably depended upon spasm resulting from the irritation of the ulcer.

436 Franklin Street.

DR. GEOFFROY, of Rome, has been administering a solution of resorcin in certain digestive disturbances, and a child in his charge died. The parents' sued him, and the medical expert summoned stated that resorcin is toxic and that an adult can not take over 2½ gm. To prove its harmlessness Geoffroy took large amounts for several days and died in consequence.

REVIEW OF THE PRESENT STATUS OF JONNESCO'S OPERATION.*

MARCEL HARTWIG, M.D.
BUFFALO, N. Y.

The olden writers considered it proper to commence an allocution with a *captatio benevolentiæ* and so do I; with what success, remains to be seen. At all events I feel obliged to make an attempt to dissuade you from harsh criticisms because my paper will necessarily fall short of my own demands; what then can I expect from you? If there be any blame, your secretary must share it with me, as his request for a paper came on a very late day, and I promised against my better conviction. Furthermore, I have to say in explanation of my choice of title, that while it is certainly wise to call an operation by a name fully expressive of the procedure, it is not less our duty to acknowledge the meritorious work of our confrères who have promoted science. The highest reward we can bestow is due to those whose genius has given us a meritorious method for alleviating human suffering. It is therefore fitting that I should call this operation—neurectomy of the cervical sympathetic—by the introducer's name.

If we desire to obtain an understanding of the effects to be expected by resection of the cervical sympathetic we must recur to the physiology of this important nerve; and here, in delving into details, we find more discrepancies than we could expect from a perusal of the text-books. Preeminently we must not forget that all results of physiologic research in animals have to be transferred with caution, into the realm of human physiology. The location of the nerve is different according to the species; and late effects have been wellnigh neglected by physiologists. While the previous observations of accidental lesions have taught us some things, Jonnesco's labors have already shed considerably more light, and he and his followers will give us still more.

Presuming that the essentials are fresh in the minds of my hearers, let me recite some rarer observations. Bidder says that after cutting the trunk the salivary gland atrophies. Gad says that electric irritation of the upper end of the severed trunk, while it remains in connection with the head, produces general contraction of the blood-vessels of the head, except those on the mucous membrane of the cheeks, lips and gums, where redness appears. Seeligmueller says that traumatic paralysis was published eight times previous to 1876; but that only twice, redness and raised temperature of cheek and ear were reported, and twice only, flattening and reduction of the substance of the corresponding half of the face. Brown-Séquard saw, 18 months after section of both sympathetics on the neck of the guinea-pig, distinct atrophy of the brain; after one-sided section, atrophy of the brain of the same side only; whereas, Vulpian only once succeeded in seeing the same result. Wagner seems to have been the first man to find (1865) that hypotony of the eyeball follows the section of the ganglion supremum, while the myosis was well-known. Panas has shown though, that this hypotony does not last. While Hippel and Gruenhagen have shown that irritating the trigeminus within the skull produces glaucoma. Abadie says that this is due to the sympathetic fibers accompanying the trigeminus.

---

*Read before the Fourth District Branch, N. Y. State Medical Association, Buffalo, May 8, 1900.

Thus, he explains the appearance of glaucoma fugax in the sound eye, after iridectomy on the diseased side, by reflex irritation of the sympathetic fibers of the good eye, similarly as the reddening of the sound side, by the irritation of the central stump of the severed sympathetic on the other side, in Dastre and Morat's experiment. If we follow the literature, of all the symptoms ascribed to section of the sympathetic in the neck the only constant one seems to be narrowing of the pupil. The latest peculiar observation is by Neuschueler (Jan. 26, 1899), who found microscopic hemorrhages in the subarachnoid space and in the ciliary body of cats and rabbits after section of the cervical sympathetic of the ganglion supremum.

After glancing at these physiologic reminiscences, let me approach our subject proper. Although Jaboulay made the first intended sympatheticotomy on both sides, Sept. 2, 1895, and although Baracz had already proposed the full neurectomy of the cervical sympathetic in 1893, Jonnesco was the first man to do the full neurectomy on both sides (1896), and up till to-day he has performed more of these operations than all other surgeons together. He is, at the same time, the man who most persistently widened the field of indications. He kept his labors constantly before the eyes of the medical world, beginning in the Comptes Rendus du Dixième Congrès de Chirurgie, 1896. His description of the operation itself, which I herewith circulate,[1] may already be called classic. Let us not forget Abadie, however, since he seems to have established the indication for extirpating the ganglion supremum for glaucoma.

The original purpose of Jaboulay was the cure of epilepsy. The theory that exophthalmic goiter is caused by an irritation in the cervical sympathetics certainly covers the field of phenomena better than any other and clearly indicates the neurectomy of the whole chain of three cervical ganglia. An irritation of the cervical sympathetics ought to produce bulging of the eyes; as removal of the upper ganglia causes retraction of the bulbi. An irritation of the lower ganglia accelerates the heart and consequently section of these slows it. There are, however, accelerating fibers in the upper two thoracic ganglia, and here may be an explanation if the operation should fail in slowing the heart. We know least of all regarding the influence upon the thyroid gland; but, inasmuch as sympathetic fibers accompany the thyroid arteries, we can at least construe an influence, little as we really know of this kind of influence. Let us not forget that this theory does not explain all, for example, why the affection is generally on both sides, or why there are *"formes frustes"* where the swelling of the thyroid is wanting, or where the bulging of the eye is absent. Let us not forget that Filehne has made the meritorious discovery that exophthalmic goiter can be produced by section of the corpora retiforma if lesion of the fourth ventricle be avoided; that other phenomena may accompany exophthalmic goiter, as the tremor and nervousness which point to involvement of the central nervous system itself; that the extirpation of the goiter alone has often cured the disease, and that thus failures by neurectomy of the sympathetic may occur. But, the results thus far are very gratifying, and last, but not least, of all surgical means neurectomy is almost devoid of danger—thus far only two deaths are recorded—while the extirpation of the goiter is very hazardous and necessitates the tying of the three or four thyroid arteries and is not better in its final effects than the neurectomy, while it does not meet the theory half as well.

The theory upon which Jonnesco attempted the cure of essential epilepsy is much less substantial. He thought, simply by producing hyperemia of the brain, to increase its nutrition and thereby possibly to cure inveterate cases, and it may be he thought of the experiments of Kussmaul and Tanner, showing that anemia of the brain produces an epileptic fit. The exasperating character of many cases of epilepsy and the well-known failure of any number of methods, the surgical included, must have led to the attempts at neurectomy, while the physiologic atrophy of the brain mentioned heretofore may have escaped his calculation. At any rate, the results have not been unfavorable as a whole, though not as gratifying as with Graves' disease and glaucoma; while the ultimate effects are, considering the novelty of the procedure (four years) unknown to-day in man.

The final results as far as ascertained and published to date, are: Jonnesco's operation for epilepsy: There were 45 cases (Feb. 11, 1899); 55 per cent. cured, 28 per cent. improved, 15 per cent. not benefited—one case cured of chorea simultaneously. Jonnesco's operation for exophthalmic goiter: Ten cases were operated on; 60 per cent. recovered, 40 per cent. improved. In one case of unilateral resection unilateral improvement followed. Shortest observation was for a period of four months *post operationem*. Jonnesco's operation for glaucoma: There were 8 cases where vision was not lost, and in each there was improvement, particularly in the glaucoma chronic simplex where iridectomy is useless. Here he removed the uppermost ganglia only, except in one case in which the exophthalmic goiter also was present. In all there were forty-two bilateral resections with no deaths from the operation. Later on six epileptics died. This is a grand record, indeed, for four years of assiduous labor, a result entitling Thomas Jonnesco to a place among the stars of the medical firmament, and to the honor of having the operation carry his name, Baracz and Jaboulay notwithstanding, although the latter's first case may have inspired Jonnesco.

Only the cool judgment of the whole medical profession can finally establish the merits or demerits of an operation. In the Société de Biologie, Dejérie criticized sharply the results obtained in epilepsy, particularly Chipault's, who, according to Schober's report, could not refute the statement that in Paris not a single cure had been obtained. Yet Professor Dupuy had also to acknowledge this. Paris having been the nidus of this operation, it does not speak well for its effect in epilepsy.

In glaucoma generally those cases were submitted in which vision was almost lost and iridectomy had been done in vain; still improvements were generally noted where vision was not entirely lost. Mohr had improvement from vision 5/15 to 5/9; field 5 to 10 degrees. Dayreux saw a failure of Abadie's. Demicheri, in Montevideo, had in three cases, very decided improvements.

Panas and Jaboulay saw the hypotonia vanish in three months and assumed that the nervous influence travels afterward through the vagus and trigeminus. Abadie saw in a case of two years' standing vision increase after several months from 1/10 on left, to 1/3, and on the right from 1/2 to 2/3, the pupils retaining their normal conditions, but in another case after a year the vision again deteriorated.

---

[1] Trav. de Neurol. Chirurgie par A. Chipault, Paris, Vigot Frères, 1897.

Dr. T. M. Ball, in St. Louis, Mo., had two improvements; but in a case of atrophy of the optic the result was nil. In exophthalmic goiter the most gratifying results were obtained by others than Jonnesco.

Jaboulay's first case, in which he removed only the middle of the trunk of the sympathetic, made a partial improvement; a second case of his improved rapidly after removal of the ganglion supremum alone, but died after ten days from congestion of the lung.

Combermarle and Gaudier report a case where the exophthalmos diminished; the pulse went down from 200 to 100; the precordial pain vanished, but the goiter remained. Gerard-Marchant saw the exophthalmos vastly diminished; Chauffard and Quénu saw no effect. We must not forget that Jonnesco himself did not extirpate the whole chain of ganglia at first, and that where it was intended, some operations remain technically incomplete, on account of the great difficulty in removing the cardiac fibers. Furthermore, some cases of Graves' disease are not primary, but the tachycardia is secondary to the pressure of a very large thyroid; here only the removal of the thyroid can cure, since the effect of the enlarged thyroid is to stretch, and thus diminish the influence of the vagus.

The number of cases I could gather in the literature accessible to me is very small, and probably this is the case in the at present inaccessible literature. After we know more of the very late physiologic effects in man, we shall know better how much risk is involved for the future well-being of a person deprived of both cervical sympathetics; and, considering the statement of Brown-Séquard about the atrophy of the brain in the animal, I do not wonder that the profession follows Jonnesco slowly. My impression is that the operation will come to stay after all that may be feared as to its sequelæ. The horrible cases of incessant epileptic fits should be operated on first, in larger numbers, as their pitiable condition permits us to consider no risk too great that holds out a prospect of relief. Here the American surgeons ought to study the late effects first; in almost blind glaucomas next, and in true exophthalmic goiter last.

If the corpora restiformia are the center of the affection, Jonnesco's operation interrupts the telegraph line, and this is the most complete theoretic basis of operation in Graves' disease. I have seen a post-mortem report which is in entire keeping with Filehne's experiment; while it is well known that changes in the sympathetic are just as often missed as found post-mortem in Graves' disease, and here, I think, Jonnesco's operation will come to stay, if it can be shown that atrophy of the brain does not follow.

884 Main Street.

THE AUTHORITIES have donated a tract of land near Moscow for the erection of a home for aged and indigent medical women. A society organized for the purpose is collecting funds to build and maintain it. Public sanatoria for consumptives are also planned at Massandra and Essentuki, and subscriptions are pouring in.

COMMON, BUT GENERALLY UNRECOGNIZED SYMPTOMS OF EYE-STRAIN.[*]

ELMER G. STARR, M.D.
Clinical Professor of Ophthalmology, University of Buffalo.
BUFFALO, N. Y.

It is now, and for several years has been, quite generally recognized that many headaches have their origin in some form of eye-strain; and persistent or frequently recurring headache without other obvious cause very soon suggests to the layman, as well as to the physician, the probability of the existence of some fault in the visual apparatus.

The truth of the relation of eye-strain and headache was not accepted at once by members of the medical profession and for a long period was slow in establishing itself in their minds. To-day, however, there are few who do not recognize this truth.

Almost if not quite as common as headache are other symptoms which are more rarely looked upon as having any relation to vision, but which should properly be classed with headaches as evidence of some imperfection in the eye.

One of the most frequent of these is pain in the back of the neck. This sensation is often described as a pulling or drawing, or a tense feeling. It is frequently mistaken for what is commonly called "muscular rheumatism." The pain often radiates down the back and to the shoulder, or may even manifest itself as a pain in the side. More commonly, however, it is limited to the back of the neck and is frequently more pronounced on one side. The statement that this condition exists is rarely volunteered by the patient who seeks the services of an oculist, because he does not think of it in relation to the eyes. Inquiry as to its existence, however, reveals the fact that it is present in about 80 per cent. of all cases of refractive error presenting themselves. I have come to consider it as almost pathognomonic of eye-strain, and rarely indeed have I seen it fail to disappear with the correction of the visual error.

Another symptom which I would class under this head is mental confusion, or confusion of ideas, or an inability to fix the attention upon a particular object of thought, without great effort. When the attempt is made to focus the attention upon some matter requiring concentrated thought, the mind soon wanders, and it is only by great exertion of the will that it is brought back again to the subject under contemplation. There may be difficulty in carrying out a line of reasoning, some part of it eluding all attempts at placing it connectedly in the line. Patients not infrequently speak of this symptom and observe that it is more troublesome the more the use of the eyes is demanded in the performance of their task.

It is worthy of remark in this connection, that, to the perfected eye found in man as contrasted with the eye of most of the lower animals, we probably owe in large measure the development of the higher faculties of our mind. For without the fovea, that small highly organized area of the retina, as found in the human eye, it would be impossible to give thoughtful attention to an object looked at to the exclusion of other objects. For to an eye without a fovea all objects in focus within the field of vision appear equally distinct. "How could we give exclusive attention to one thing if all other things were equally distinctly seen? Thoughtful attention to the object looked at seems to be a necessary condition of the emergence of the higher faculties of the mind. Concentration of thought on the object thought of is a necessary condition of effective thought work." (Le Conte.)

---

[*] Read before Fourth District Branch New York State Medical Association, Buffalo, May 8, 1900.

Closely allied to this condition of disturbed mental processes which I have mentioned, and possibly in part depending upon it, is mental inaptitude or backwardness in children. Comprehension seems obtuse and slow. Frequently this condition develops rather suddenly in a pupil who has previously had no trouble in keeping his place with his class, and is then often accompanied by headache and other nervous manifestations. The correction of an existing eye-strain changes all this. School work is done more easily, and frequently the child is wonderfully changed mentally and physically. Instances are common where a child is backward in his classes in school simply because of the effort required to see distinctly. By this I do not mean to imply that vision is not distinct for all distances, but that clear vision is attained only through the continuous exertion of a great amount of nerve force. In fact the possession of distinct "sharp" vision by a person is no evidence that his eyes are free from imperfections and that they are not working hard to maintain good vision. In short "good vision" does not mean "good eyes" although it is usually so considered by the laity.

As illustrating this condition I will give briefly the history of a boy 9 years of age, who until within six months of the time of this history was able to do, without difficulty, the work required of him in his class in school. Now, at the time of his visit, he seems quite incapable of doing the same work done by the other pupils of his class. He is listless and seems slow of comprehension. His appetite is fickle, and sleep is disturbed. He is pale and is losing in weight in spite of the tonics which he is taking. Latterly he complains of headache and occasionally of blurred vision; which latter complaint impelled his mother to bring him for an examination of his eyes. A high mixed astigmatism was found and correcting glasses given. The use of his medicine was stopped, but his glasses were worn constantly. Within a week an improvement in the boy's condition was observed; his school work was resumed and performed without trouble, while his physical condition showed a great improvement.

Irritability is another common result of eye-strain in adults as well as in children. We are all liable to become irritable to the verge of irascibility if overworked, and it is easy to see how a nagging eye-strain kept up hour after hour for days and months may so draw on the nerve-supply as to lead to the same result.

Vertigo is a symptom frequently associated with vision. It may be the result of some marked muscular anomaly, or, more often due to a refractive fault. The vertigo may be transient and infrequent or may be very marked and persistent, so much as to suggest grave intracranial disease. It may bear a close resemblance to Ménière's disease. Many individuals having vertigo present with it that symptom which is characterized by a dread of crowds or congregations. Often great effort is required on the part of these persons to remain quietly in a church or theater filled with people. A feeling of impending danger or the fear of an attack of fainting, or an ill-defined sense of apprehension impels the unhappy sufferer to leave the room to get relief from these disturbing feelings. This may be one of a group of symptoms embraced by the term "nervousness." A very high proportion of those who come to the oculist with refractive errors admit themselves to be nervous.

A case that well illustrates the fact that vertigo may be the result of eye-strain is that of Mrs. V., married, aged 37, who had had constant vertigo after a sudden onset, for ten days. Nausea with some vomiting accompanied it. The distressing symptoms were aggravated by turning the head or body toward the left; especially was this true if done while lying down. These symptoms grew worse and became so distressing that the attending physician feared some brain disease existed and called counsel to aid in making a diagnosis. Eye-strain was suggested as a possible cause of the trouble and as soon as it could be done the refraction of the eyes was measured. They were found to be unsymmetrical. One eye had moderately high compound hyperopic astigmatism, while the other had a mixed astigmatism; the astigmatic axes were unsymmetrical; a slight muscular imbalance also existed. Correcting glasses were at once prescribed and the distressing vertigo gradually disappeared. Some months later, because of an accident to her glasses, the patient was without them for several days, when a return of the vertigo made her hasten to get new ones, which promptly gave her the desired relief. A fact worthy of note in regard to this case is this: Almost at once when the eyes were placed completely under the influence of the mydriatic there was a diminution in the severity of the symptoms, i. e., as soon as the eyes were put to rest by the mydriatic the reflex disturbances began to lessen; and I am sure that very valuable help may be had by the physician in the use of a mydriatic in making his diagnosis, in many cases of suspected eye-strain. A transient mydriatic like homatropin should be used, and some precautions should be observed, such as not to use it in too old subjects, nor in eyes where tension seems greater than normal.

Another rather interesting condition which I frequently find, apparently depending on eye-strain, is a varying or fluctuating character of the handwriting. The writing in the beginning of a letter may be regular and smooth, but after a few minutes its character changes, and becomes more irregular, angular and jerky,and less legible. This condition is found most often in those who do much writing, and I mention it more for its interest than for its importance.

Probably the most frequent of all the results of eye-strain in its various forms is seen in disturbances of the digestive apparatus. For the past eight years I have been careful to make inquiries of patients having refractive or muscular imperfections as to the condition of their digestion, and in the majority of all those who come with refractive errors or visual strain of any kind, I have found a history of some form of indigestion, so-called. Following the progress of a large number of cases, I have seen the digestive disturbances disappear more or less promptly with the correction of the visual defect. In so many instances has it been observed that a recurrence of the symptom follows the disuse of the glasses, or is the first evidence of the need of a change of glasses, that the fact of cause and effect is surely established, and it is abundantly demonstrated that very many cases of digestive derangement have their origin solely in the organs of vision.

A case in illustration of the foregoing is that of Mrs. J. D., a married woman, 37 years of age, who had a serious stomach and intestinal indigestion for 1½ years prior to her eye-examination in May, 1896. I have no analysis of the stomach contents made after a test-meal, but that the function of the stomach was greatly disturbed may be inferred from the fact that at the time of her examination the stomach retained nothing, not even water, longer than twenty minutes. For more than a year she had been under the care of a physician, and had spent three months in a hospital, where she was placed upon the strictest dietetic regimen, and where all resources were exhausted in the attempt to correct her distressing conditions. An examination of her eyes revealed an astigmatic condition, unequal in the two eyes. The muscles were normal in balance. The effect of correcting this eye-strain with glasses was marked. Within twenty-four hours the intense irritability of the stomach and the nausea had almost entirely disappeared; and within a fortnight the patient was eating a varied diet and was free from all symptoms of indigestion. She remained well for more than a year, when some symptoms of returning indigestion prompted her to come for another examination. A slight change in the astigmatism was found and corrected, whereon the disturbing symptoms promptly disappeared.

In the foregoing I have not taken extreme cases to illustrate the conditions, nor extreme conditions for my subject-matter, but have confined myself to a few common, as I think, conditions resulting from eye-strain. a statement which any physician can soon verify for himself. It may be that this matter is familiar to most or perhaps all of you here, but that it is not generally familiar to the medical profession I have many times had impressed upon me by my experience with patients, and this is my reason for presenting it.

523 Delaware Avenue.

DISEASES OF THE PANCREAS.

REVIEW OF THE PRESENT STATUS OF KNOWLEDGE CONCERNING THEM.*

CRAYKE PRIESTLEY, M.D.
DES MOINES, IOWA.

The difficulties in diagnosing pancreatic affections are so numerous and gigantic that we rarely find a case in literature where a correct diagnosis has been made before operation or necropsy. However, there are some, and this fact should prove a powerful stimulus to all medical men in their study of this organ. Within recent years, more attention has been given to the pancreas than hitherto, and with results quite gratifying. To these the writer wishes to call attention, with the hope of arousing greater interest in these affections.

Pancreatic hemorrhage may occur as small infiltrations diffused through all or a part of the gland, or it may consist of a large effusion of blood into the gland and the surrounding tissues. Anders[1] has collected 40 cases of pancreatic hemorrhage, and in all except 1, there was hemorrhagic infiltration into the gland itself. In 17 cases, the structures around the pancreas were infiltrated, in 12, the retroperitoneal tissues, and in 5, the lesser peritoneal cavity. This affection is more common in males of rather advanced years. In Anders' collection, mention is made of the use of alcohol in the anamnesia of 14 cases, of dyspepsia in 3, of jaundice in 2, and of traumatism in 3. Heart lesion was found in 2 cases, and primary carcinoma in 1. The attack begins suddenly with severe colicky pain in the epigastrium, vomiting, and all the manifestations of profound shock; death follows very shortly, sometimes immediately, and usually within forty-eight hours. A diagnosis is seldom made before the necropsy.

Of acute pancreatitis we have three recognized varieties; the homorrhagic, the suppurative, and the gangrenous.

In the hemorrhagic form, the organ is enlarged, is of a chocolate color, and shows circumscribed and diffuse infiltration of blood in the interstitial fat tissue. Disseminated fat necrosis is also frequently seen; this consists of numerous small or large, white, opaque areas, situated within the gland or in the subperitoneal fat tissue. This peculiar necrosis is found only in affectons of the pancreas. A. Katz and F. Winkler[2] conducted a series of experiments on dogs—fifty-one in number—in which they tied, and then divided the ducts of the pancreas. They found, as a result, marked fat necrosis most pronounced in the areas nearest the ligatures, consequently they concluded that the necrosis is due to the fat-splitting ferment of the pancreas. Hemorrhage was almost invariably found around the areas of necrosis; and it is probable that this increased the tendency to necrosis by lowering the vitality of the affected tissues. The symptoms are sudden, violent, deep-seated pain, and great tenderness in the epigastrium. Fever is moderate. There is a rapid pulse and anxious expression—indications of collapse; also vomiting and constipation or a fatty diarrhea. Jaundice may be present, and is due to pressure of the swollen head of the pancreas on the common duct. The prognosis is bad but not absolutely hopeless, as recovery has been known to take place. Osler[3] records a case which was diagnosed as intestinal obstruction. The abdomen was opened and acute hemorrhagic pancreatitis discovered; the abdominal wound was closed and the patient recovered. This proves beyond all doubt that recovery may ensue, and it is an open question whether these cases are not sometimes considered as biliary colic and go on unrecognized to complete recovery.

In acute suppurative pancreatitis, we find either one large abscess occupying the head, body, or entire organ, or numerous small areas of suppuration scattered throughout the gland. The abscess may rupture into one of the adjacent hollow viscera, in which case broken-down pancreatic tissue might be found in the stools. The infection probably extends from the duodenum along the pancreatic duct into the gland, and there is frequently a history in these cases of repeated attacks of gastroduodenitis. Peritonitis may result from the rupture of one of the small abscesses, or pleurisy from the extension of the inflammation through the diaphragm. In the suppurative form, the symptoms are usually not so severe nor acute, and pain may be slight or absent. Evidences of septicemia become gradually more and more pronounced, there are chills and sweats, with a very irregular temperature and a progressive cachexia; jaundice may appear, as may also fatty stools. The disease runs a course usually of several months.

In gangrenous pancreatitis, the gland frequently presents the same appearance as in the acute hemorrhagic form, except that there is a circumscri[illegible] gangrenous area. When the gangrene is extensive, the whole organ may be destroyed. It is found to be a dark brown, soft, shreddy, decomposing mass, loosely attached, or even floating freely in a thin, purulent, foul-smelling fluid which is contained in a sac, formed by inflammatory exudate and the adjacent peritoneum. As in the case of abscess, a communication may be formed with the bowel and the sac contents, and pancreas and all may be evacuated through this channel. Trafoyer[4] reported a case in which the pancreas was discharged per rectum and the patient lived seventeen years afterward. Fat necrosis is usually very extensive in cases of gangrenous pancreatitis. The symptoms are practically those of acute hemorrhagic pancreatitis, but the course of the affection is somewhat more protracted.

---

*Read before the Iowa State Medical Society, Des Moines, May 16, 1900.

There is another condition to which attention should be given, but before proceeding further, permit me to record the notes of two cases.

Case 1.—G. H., a male, aged 25 years, with previous history good, noticed pain and swelling in the right parotid region, Jan. 18, 1900; this increased on the following day and the left side became involved. He came under observation January 21, when he presented a typical case of mumps. He was seen again January 25, by which time the parotid swelling had almost disappeared. The temperature was 100, the pulse 80, and the patient complained of a pain and aching in the epigastrium and of very distressing nausea. January 26 the temperature was 101, the pulse 105, and the pain in the epigastrium was intense and accompanied by very great tenderness. He vomited eight times, but the bowels had not moved, nor had he taken any nourishment for over forty-eight hours. The pain was so severe as to require the hypodermic administration of 1/4 gr. of morphin. January 27 the temperature was 100.6, pulse 105, and pain and tenderness in the epigastrium still great but not so intense as on the previous day. He vomited once and had several spells of retching; the bowels moved after he had taken 10 grains of calomel; but on the whole, he was very miserable. January 28 the temperature was 99, the pulse 80, and the pain and tenderness in the epigastrium had moderated considerably, though still present and distressing. He took a small amount of milk, and did not vomit or suffer greatly from nausea. January 29 the temperature and pulse were normal, and he felt much better and relished food. There was not much pain, but the tenderness in the epigastrium still remained. From this time on he improved very rapidly, the tenderness disappearing entirely after about three days.

Case 2.—J. McQ., a male, aged 14 years, had the mumps on the left side only. The disease appeared February 12, but he was not seen until February 16, when the parotid swelling was scarcely noticeable. He complained of severe headache and pain in the epigastrium. The temperature was 102.5 and the pulse 80. February 17 he vomited five times, and the pain in the epigastrium became more severe, and later quite agonizing, and was accompanied by nausea and exquisite tenderness; the temperature was 102.5, the pulse 90. The parotid swelling had entirely disappeared, but he had complete anorexia and obstinate constipation. February 18 the temperature was 100, the pulse 80, and he vomited twice; the pain and tenderness in the epigastrium were severe, but not so bad as on the day before. A small, hard passage from the bowels resulted from a large soapsuds enema. February 19, the temperature and the pulse were normal, and the patient was much better and hungry. There was no pain, but some tenderness in the epigastrium, which continued for two days.

In the foregoing cases, we have all the symptoms of an acute, though brief attack of pancreatitis, and in view of the great similarity, anatomically and physiologically, between the parotid and the pancreas, we are justified in considering that in these cases there was a pancreatitis due to mumps, similar in every way to the parotitis so commonly seen. This may be due to a metastasis, such as not infrequently occurs in the testes, ovaries, and mammæ; or, what seems even more probable, may be due to a secondary affection, the infective material passing through the stomach into the duodenum thus gaining access, through the duct of Wirsung, to the pancreas, as it undoubtedly does through Steno's duct to the parotid. The urine and feces were examined in both cases with negative results; however, when the pancreatic involvement is of such short duration, and is followed, as it undoubtedly is, by complete restoration of function, we could scarcely expect to find evidences of the disturbance in these excretions. There is no way in which this theory can be proved, but the notes of several other similar cases indicated that the explanation given accounts for the symptoms described. H. F. Harris[5] reported a case of diabetes that quickly followed the mumps in a man, aged 42 years; he also found several references in the literature to the fact that this happens not infrequently. It is well known that sometimes mumps produces permanent destruction of the parotids, and it is no more than reasonable to suppose that, in this instance, there was a pancreatic involvement which terminated in complete, or almost complete, destruction of the pancreas. This case tends greatly to strengthen the supposition in regard to the cause of the symptoms in the cases recorded in this paper, and to prove that instances of pancreatic mumps are not at all rare. This can not be proved, because it is seldom indeed that permanent changes result from mumps; and where these changes are not permanent, the organ, after a few days, returns to its normal condition, in which event all symptoms quickly subside. No mention of these cases is to be found in the standard text-books or in current literature, and notes of any would be very interesting.

The treatment of all forms of acute pancreatitis is purely symptomatic, except in the suppurative and gangrenous forms, where, if the condition be recognized, surgical interference may prove serviceable.

Chronic or indurative pancreatitis presents an overgrowth of the connective tissues of the gland with destruction of the parenchyma. A part or all of the organ may be affected. It is hard and indurated, with a smooth surface, and on section, large fibrous bands are seen surrounding or replacing the lobules of the glandular tissue. Fatty degeneration of the cells occurs and here and there may be seen small white spots, due to the accumulation of crystals of the fat acids or deposits of calcium salts, while Wirsung's duct is usually enlarged and sacculated.

The causes given are alcoholism, chronic inflammation of the pancreatic duct, due to repeated attacks of gastroduodenitis, or anything causing obstruction of the duct such as calculi or the pressure of adjacent neoplasms.

The disease begins slowly with the symptoms of chronic gastritis; then comes deep-seated pain in the epigastrium, occurring paroxysmally and accompanied by considerable prostration and great anxiety on the part of the patient. No doubt many cases in the earlier stages are mistaken for chronic intestinal indigestion with acute exacerbations. Jaundice may exist and is usually permanent; it results from pressure by the head of the pancreas on the common duct. Constipation is the rule, but may be interrupted by sharp attacks of fatty diarrhea, and these stools may be colorless even when jaundice is not present.

Glycosuria has frequently been found in cases of chronic pancreatitis, and a few years ago it was thought that in this disease we had at last discovered the origin of diabetes; but this belief, however, was short lived. It has been proved that complete removal of the gland always causes marked glycosuria. If from one-eighteenth to one-twelfth of the gland remains intact, glycosuria is present but not pronounced, while if one-tenth is allowed to remain, glycosuria does not necessarily occur. Thus we see that before sugar appears in the urine as a result of pancreatic lesion, very extensive destruction of the gland must have been brought about. The changes in the gland are permanent, so the treatment must of necessity be to relieve, as much as possible, the symptoms. The administration of minced pancreas has been said to be of value.

Pancreatic calculi are formed of calcium salts, either the carbonate or phosphate, and are generally the result of a chronic inflammatory process of Wirsung's duct, or of some obstruction of the duct from any cause whatsoever. The stones vary greatly in size and number; they may be as fine as sand and be almost innumerable, or there may be one calculus as large as a walnut. Occasionally they ulcerate through into the stomach or bowel and may be found in the stool. They may be so large or numerous as to cause complete obstruction of the duct, in which event a cyst results, or they may pass through the duct, giving rise to pancreatic colic which may be indistinguishable from biliary, unless glycosuria or free fat in the stools should be discovered. Jaundice is common during or after pancreatic colic, thus making the diagnosis even more difficult. The treatment is the same as for gall-stones.

Pancreatic cyst may be congenital, but more frequently it occurs in adults. Von der Haan[6] has reported the only case of a cyst in a child, due to traumatism, the usual cause being an obstruction of the pancreatic duct or one of its branches. If Wirsung's duct is obstructed, one large cyst which may destroy the whole gland results, while if several of the contributing ducts are closed, we may have numerous cysts of small dimensions, the remaining portions of the gland being unaffected and functionating normally. Hematoma are not infrequently the origin of cysts, and traumatism also may result in cyst formations. The consensus of opinion now, however, leans toward considering these as instances of encysted peritoneal effusion, involving the omental bursa. The fluid of pancreatic cysts has a specific gravity of from 1010 to 1026, is of a grayish color, cloudy, and alkaline in reaction. Microscopic examination shows fat globules, epithelium, leucocytes and crystals of cholesterin and the fatty acids. If the cyst is large, we have pressure symptoms such as epigastric pain, jaundice and ascites in addition to the disturbance caused by the absence of the pancreatic secretions in the process of digestion. Vomiting and constipation or fatty diarrhea may be present, and if extensive destruction of the gland has taken place, glycosuria may appear. The tumor, when large enough to be palpated, feels round and smooth, is slightly movable and lies usually between the stomach and the transverse colon. Inflation of the last mentioned organs may aid in locating the cyst, but aspiration of the tumor is a very dangerous procedure and not to be advised, since the treatment belongs to the domain of surgery.

The next and last disease we have to consider is carcinoma of the pancreas. This is generally primary, and occurs more frequently in males than in females, and—as is the rule of carcinoma of any part—in persons past 40 years of age. Scirrhus is the most common form and the head of the organ is most frequently affected. The density varies; if the fibrous tissue predominates, it is very hard and, if degeneration has taken place, it may be even mushy. The neighboring organs and tissues are generally affected either by direct extension of the growth or by metastasis. If the duodenum is affected or pressed on, the stomach becomes dilated, and the portal vein may be compressed and give rise to ascites. Pressure on the inferior vena cava causes anasarca of the lower portion of the body; and if the common duct is involved, intense and permanent jaundice results, accompanied by dilatation of the gall-bladder and enlargement of the liver. If the tail of the pancreas is the seat of the growth, left-sided hydronephrosis may result from pressure on the ureter. (Fitz.)

The disease is seldom recognized during life, but there are some signs which if discovered may lead to a correct diagnosis. These are glycosuria, a deep-seated tumor in the epigastrium, and the presence of undigested muscle fibers in the stools when no diarrhea exists, which is always an indication of the absence of pancreatic secretions.

The prognosis and treatment of pancreatic carcinoma require no discussion.

SYMPOSIUM ON DENTAL EDUCATION.[*]

DISCUSSION.

DR. G. V. I. BROWN, Milwaukee—I am sorry Dr. *Hill* is not present to take part in the discussion of this subject, as his paper is not a set of phrases put together for the day or the time, but is based upon his own practice. Dr. Hill, a physician, is better capable of discussing the pathologic conditions, local and general, that have relations to affections of the mouth than almost any dentist that I know. He sends a great many patients to me; almost every case is diagnosed, and very rarely, if ever, do I find reason to change the diagnosis.

DR. CRYER.—Being only a visitor to this Section, and not having heard all the papers read upon the subject, there is but one point on which I can speak. Throughout the reading and discussion of papers in dental meetings, there seems to be a tendency for the dental profession to find fault with the medical profession for their treatment of the dentists. In my association, as a dentist, with the medical profession, and when I attend their medical meetings, I am treated with the utmost courtesy; when the dental profession is spoken of it is with the greatest respect, and it is constantly recognized according to its worth.

It is claimed by your speakers here to-day that dentists are not recognized by the medical profession. Do we recognize the medical profession as we should? We constantly claim that dentistry is a specialty of medicine as is ophthalmology or laryngology; yet, in Rhode Island, a graduate of the University of Pennsylvania in medicine and dentistry was arrested and taken into court through the *instigation of the* dental profession of that state, for practicing dentistry without a license. He had taken out the license to practice medi-whether to send the patient to a dentist, or to treat the case himself. I do not think the physician should feel that it was for him to pass upon the dentist's work. A lady came to me from an adjoining city. She had a gold crown on a central incisor. I removed the crown, not that I expected to find anything wrong with the tooth, but because the crown was so conspicuous. Under the beautifully polished crown I found a broken brooch extending into the pulp. Not until I had removed this brooch did I learn that the lady had had neuralgia. I give this instance to illustrate how impossible it would be for a physician to judge the dentist's work. I could not have known that anything was wrong till the crown was removed, and certainly a physician could not. In my own personal treatment by physicians I had nothing to complain of. They always treated me on the plane of equality, as a specialist. Whether others are met in the same spirit I do not know. I think, that as a rule, the dentist is correctly looked upon by the physician. When the average dentist makes himself more competent and thorough he will get the credit due him.

---

[*] This discussion is on papers presented before the *Section on Stomatology*, at the Fifty-first Annual Meeting of the American Medical Association. THE JOURNAL, vol. xxxiv, page 1661 et fol.

The time when a dentist should get the manual training needed in his practice is a difficult question to decide. Some think he should get the M.D. degree before studying dentistry, This would bring him to 24 years of age and perhaps 27, before he gets the baccalaureate, M.D. and D.D.S. The man who reaches the age of 24 before he studies dentistry will never make a good dentist. It would be better were the training to begin before he leaves the high school.

Dr. John S. Marshall, Chicago—About three or four months ago, the secretary of the Section called on me to talk over the question of dental education, and suggested a symposium on the subject. As there were two opinions prevalent in relation to it—one that the dentist should be medically educated, the other that a medical education is not necessary, it was thought expressions from a few of the prominent men in the profession on the subject would be of great benefit. Dr. Talbot then invited these gentlemen to prepare papers. He called on Dr. Davis for a paper, because he knew his position, which is as follows. If the dentist is a specialist in medicine he should be educated as a medical man. He also spoke of the status of the profession and of its recognition by this Association and of the arguments which were brought to bear on this Association in order to obtain that recognition. I believe this Section has done as good work for dentistry as had any dental association in the United States. The character of its papers are as good and better than those presented before the National Dental Association. Besides this there is no politics. We come together for purely scientific work and labor through the whole session to that end.

I am sorry that Dr. Taft's paper is not here. Dr. Taft was asked to write on "Preliminary Qualifications," a very important subject. I touched it lightly in my own paper under the head of "Recommendations." I think that to-day entrance qualifications are too low and ought to be raised. The best way to raise them is to require a medical certificate. As to when the manipulative skill so absolutely essential is to be acquired, I think that Drs. Bogue and Hatch lost sight of the fact that 50 per cent. of the medical student's training is laboratory work which requires his fingers and his eyes to be constantly employed. He gets as much manipulative training except in gold work as does the dental student. He is trained from the first, in the medical class, to use his hands and eyes, and to use them intelligently. I have always held to the view that the only correct way to educate a dentist is to first educate him in medicine, then in dentistry, his specialty.

In Dr. Peck's paper great stress was laid on object teaching. He spoke of vivisection to show the action of drugs and its great value in impressing on the mind of the student the action of the heart, lungs, etc. A student who has seen these things never forgets them. It makes a tenfold deeper impression on his mind than reading.

Dr. Brown's paper was along similar lines, though he tried to show that the two courses of instruction, medical and dental should go together. This idea was carried out in one of the schools in Chicago. The plan was to have the medical and dental students take up the very same course of instruction and the same examination, teachers not knowing the medical from the dental students. In the first and second ye the dental students had some training in the mechani laboratory, and the third year was devoted to purely mech ical and operative work. He believed that that school tur out some of the brightest men to be found in the dental p fession to-day.

Dr. Steeves laid some stress on the necessity of a medi education. She has not this education herself, but has b in practice long enough to discover how much better it wo be for her if she had.

Dr. Hill, after pointing to the interdependence of the d tist and the physician, said, to-day in most of the dental c leges they are teaching technique to the exclusion of scien turning out splendid jewelers and artisans, but very po scientific dentists.

I do not desire less time given to manipulative traini none give too much time to that, but the students should more scientifically trained. One young man, a graduate one of the best scientific colleges of the country, being ask What would you do, suppose you were called upon to see child in convulsions from an erupting tooth? said, "I wou give 15 grains of chlorate of potassium." Being asked wh he expected to accomplish by such a dose, he said he didn know. Another case: A lady who had been an assistant f seven years in a dentist's office took her little child to a de tist, also a graduate of a first-class institution, to have hi examine the central incisor teeth. The child had been ill a the enamel was unformed on the cutting edges; she to the child to find out whether it was better to file these tee down or allow them to wear down. The dentist said, "It w be only a little while before the enamel will grow over the enc just see how it is growing now. Both of these young fellov I am personally acquainted with, and they are both fi manipulators. They make as beautiful gold fillings as an man in this room. These are facts, and they explain why much stress is laid on the need of scientific training. I do n say it was the fault of the teaching in the colleges that the men did not have this knowledge. They probably were taugh them, but in the examinations there should be some way c finding out whether they were learned or not. It's a disgrac to the profession, and I feel ashamed that any school shoul graduate such men. In regard to what Dr. Rhein said, w almost always hear when anything is said of indivdu training of the dentist that medical men are to blame fo their condition. "If the gentlemen who applied to the medic college in Baltimore, wishing to establish a dental cha had had their offer accepted, there never would have bee any dental schools." Ask yourself the question: How muc science was there in dentistry in 1846? Was it not a hand craft, a purely mechanical calling? What was known of scientifically at that time? Compared with what we hav to-day, it was simply nothing. He did not think it was righ to blame the medical colleges for this refusal. They acte according to the best light they had at that time.

In his paper Dr. Rhein called attention to the fact that th principles of dentistry should be taught in medical school This has been done. The first medical school that did it wa the Cincinnati School, beginning in 1870 or '72; the Syracus Medical Department was the second in 1879. Dr. Marsha had the honor of being elected to fill this chair. In Chicag all the medical schools established a chair of dentistry in 18 or 1883. I was elected to the chair in the Chicago Medic College. All these schools, with one exception, still maintai these chairs. I do not know whether the medical schools i New York have such chairs or not.

Dr. James Truman, Philadelphia—The question as raise by Dr. Andrews, seems to me to be one of the most importan that the dental mind can take up at the present day. I con tinually ask myself the question: "Whither are we drifting Are we drifting toward medicine, or are we going back to th original standpoint of dentistry?" I believe that the profes sion is gradually drifting toward the M.D. degree, and that i will not be many years before dentists will lay aside th D.D.S. entirely. I am sorry that this is so, for I believe tha in proportion as we aspire to build up our curriculum so a to produce M.D.'s, just in that proportion will dentistry deteriorate. This view is based upon an experience of a good many years as a dental educator. I have found that in proportion as the standard of education has been raised, just in that proportion have we deteriorated in our dental acquirements. This may not be an agreeable thought to many, but we can not resist the logic of facts and I look forward to the result of further advancement with dread. Dr. Marshall stated that in proportion as a student is trained in medicine he makes a better dentist. I know that this was not a fact. I have helped to train many medical men in dentistry, but they were almost universally failures as far as dentistry was concerned. It has been well stated that the older a man is the more difficult it is to develop manipulative skill. The work in medical colleges does not teach technical ability. A man can only be taught at the bench to make a success in dentistry. I feel very strongly on this point, and am sorry I have not time to elaborate it, but to me it is very clear that if we go on and add every year to our curriculum, we are going to make very poor dentists. I would like to get the question down to practical details and discuss it in its broadest aspect. In my own school the dental students work right along with the medical, for the first two years, and since this rule has been adopted, I think they made poorer dentists than ten or fifteen years ago. I hope the Section, after further consideration, will see the question in this light, as I am convinced that dentistry is losing ground rapidly by so enlarging the curriculum that the students can not digest it.

Dr. A. E. Baldwin, Chicago—I am glad to have heard Dr. Truman, though I do not agree with his conclusions. I am going to speak of the two professions drifting together, but with a different conclusion. The trend of the two professions seems to be to get closer together. It seems contrary to reason to say that a man will not be better because of more extended knowledge, or in other words, that it will take from my manipulative ability, to know of the physiology, pathology, or the histology of the parts of the human frame upon which I work. It seems to me that the greater my knowledge in these particulars the greater will be my efficiency as a dental adviser. There are a great many things to be taken into account, but these are vital.

I find the dentists are gradually getting over their antipathy to medical men. They are generally recognizing the fact that we are both on the same ground. As we get over this feeling we shall find ourselves becoming broader and better professional men.

Dental education is not primarily manipulative, but our schools should aim to teach, first, what the conditions we find in the mouth mean, and to discover their causes, and the methods of ameliorating them; besides this it is important the student should be placed in a receptive state, so that he may go on with his dental education after he graduates. I do not want to detract from the importance of the manipulative skill. This the student must acquire, but the other is of primary importance.

I would like to know why a medical graduate is a poorer dentist than one who is not. This statement was made fifteen years ago in connection with a school started in Chicago for the purpose of teaching dentistry to medical men only. One of the teachers in that school made the statement at a dental convention several years afterward that the students of that school were very hard to get along with. They could not be taught much, as they thought they knew all there was to know. My private opinion is that with a different corps of instructors the students would have had a different experience. If the teachers had been fitted to teach them the advanced course beginning where the medical course had stopped, they would have been successful, but to teach graduates of the medical college a new pathology, a new bacteriology, and a new physiology was of course uphill work.

The best way to get recognition from medical men is to get in line and recognize work done by them and get our profession in line to advance to the knowledge medical men have. Dr. Rhein speaks of the importance of manual and technique training. It seems to be proper that these should be conducted in a co-ordinate department; but in any case we can not make a good dentist of every student. Some men would be successful as physicians who would never succeed as dentists; others would succeed as dentists who would fail in medical practice. The selection should be made before the student enters college. In truth, not all dental schools are conducted on a professional basis. Some of them are purely financial institutions with the idea of getting as many students as possible; as long as we have that kind of schools we must expect to have trouble with the product.

Dr. W. B. Hill, Milwaukee—I want to plead for the dental education of the physician. You have said he ought to be educated, but I do not know who is going to educate him. I am willing to sit at the feet of any one who will teach me about the mouth. A considerable proportion of the medical profession are looking in vain for some one to teach them. There are those who are competent, but they are not common; and they have not been brought to us. The dentist should be as is the oculist; and physicians would go to him for knowledge as they do to the oculist. We do not go to our fellow practitioner to learn of the eye, nor do we go to the oculist to learn how to fit spectacles, but we do ask him to teach us of the eye that we may know and recognize disease, that we may note disease in preliminary stages, and refer such cases to the proper one for the work. This is what we ask of dentists as to the oral cavity.

I have been studying dentistry for several years and to a certain extent have established myself as a censor on dental work. I not only refer patients to the dentist, but I take them to the dentist and together we determine what is to be done, and together we watch the results, and I am happy to say that we generally cure the patient. But in cases where the work is not done in consultation, work that is referred to the dentist, I think it proper, if the doctor has any dental education, any knowledge of the mouth, that he should see that the work he has ordered is done correctly. I have had a few cases in my practice that emphasize this necessity. One of my patients came to me from a dentist. She had had a tooth filled and was suffering intensely. The dentist told her that if he (Dr. Hill) would give her a little morphin to stop the pain for a few hours, the tooth would be all right; he refused to furnish the morphin and sent her back to the dentist. The end of the matter was that the filling was taken out and the tooth properly treated before the trouble was settled. I relate this to show that physicians ought to know when patients are properly treated by dentists. It is true they might not discern some of the hidden things, but they would be pleased to discern the hidden things that we are capable of if they could be educated on the line of diagnosis. It is no harder for a physician to diagnose from symptoms the involvement of a tooth pulp or the presence of a calculus in it, than it is to determine inflammation of the appendix. I make the plea that medical men should be educated, and the dental profession should train up a lot of men to be specialists in the oral cavity so as to train the medical profession; they need it. It is true in the medical profession we make slighting remarks of yours. This is caused primarily by the ignorance of the physician making the remark, and secondly by the poor training of large numbers in the dental profession.

Hippocrates stated, I believe, that medicine was an art, and there are people who think that if Hippocrates made this statement that it was the truth and has remained true through all these centuries, but it is not true now, although it was then. Now it is a science. Dentistry is a combined science and art. These two can not be divorced, the science being the science of medicine. If we would teach scientific dentistry it is impossible to divorce the mouth from the rest of the body. It is a part and parcel of it. The same blood that circulates in the mouth and teeth circulates in the extremities, heart, liver, and kidneys. If you would be a man to whom we can trust the treatment of the oral cavity, with all its ramifications, with all its nerve supply, with all the possibilities for irritation and remote nervous manifestations you must understand the whole body, and make a study of it in its completeness. If on the other hand your profession is to be one which has to do only with treating the teeth and filling cavities, then it must take the position of being an art merely. The work must under the directing hand of a physician who is competent to judge of the conditions of the mouth as well as the rest of the body.

It has been said that to have a practitioner of dentistry take a complete course in medicine would require so many years he would be too old to acquire the technique which is necessary in dentistry. I believe not that a man should first make of himself a physician, begin practice, then change his mind and go back to learn dentistry, but that he should begin to study with the idea of being a dentist in the highest acceptation of the term, with an educational foundation broad enough to reach any height in his chosen profession. The dental and medical training can be done at the same time and there is no reason it should not be. I do not know who was responsible for the divorce of the dental and medical professions; the question is, how shall we get together? I believe it can best be done by such a course of study as I suggest. W can work toward it and bring the dental and medical students together. We can educate them in the same classes and make them pass the same examinations, and the two boys who have stood shoulder to shoulder in the lecture room will have respect for each other in professional life.

I do not believe with Dr. Truman, that a higher education is a menace to the profession of dentistry. A dentist is a scientific man who has not only his head trained, but also his heart and hand; if this be true, he can not be too highly educated. He can not have a culture too great to enter this profession. My ideal dentist stands head and shoulders above the practitioner of medicine—a man who knows all the physician knows, and his special knowledge beside.

I suggest that we set up the high ideal of the specialist in medicine, and secondly, take in for education the very best talent, a scientific mind, a cultured gentleman, and a deft hand, being the requirements; and that we carry on this education of the physician and dentist if possible, in one institution, giving them both the same foundation, allowing the dentist to add to this the practical work in the laboratory, in the infirmary, in the hospital and in the clinic, until he stands a specialist who is competent to consult with any physician, and thoroughly capable to carry out the desires of the physicans in the treatment of their patients.

Dr. Wilbur F. Litch, Philadelphia—I can confirm from my own experience the statement made by Dr. Truman, that a physician entering a dental school usually makes a very poor dentist, but I do not accept the conclusions which Dr. Truman drew from this fact. In the selection of a vocation or of a specialty, the line of least resistance is followed, and as a rule, that is the line of personal aptitude. The man who, after passing through his school-boy days, determines to be a physician is probably not very highly endowed with mechanical skill. The same may be said of the man who resolves to devote his life to commerce or other non-mechanical callings. Hence, I do not think that the physician is more likely to make a poor operator than the man who comes from trade, the pulpit or the bar. The physician makes a poor operator because he has not been trained from his youth in manipulative processes, not because he has studied medicine. I fully agree with Dr. Bogue that the highest skill in technique, that perfect adjustment of co-ordinate muscular movement which constitutes knack, is attained only where the training is begun early in life. This is well illustrated in piano playing, perhaps the most difficult technique the human organism has been forced to master.

Dentistry is peculiar in the fact that it requires such a high degree of complex technical skill, conjoined with a good degree of scientific knowledge, and the problem is how to arrange our courses of instruction so as to secure these combined results. If we start with medical instruction without any preliminary training in dental technique, there will be that loss of skill which is the result of insufficient training in early life. It is, however possible to arrange the courses of study so that this objection may be, in a measure, overcome. Possibly most of those present have seen the paper of Professor Bowditch, read in Washington before the Medical Association, entitled, "The Medical School of the Future," in which he outlined the difficulties of the situation as regards overcrowding, and the overrating of medical courses, and stated that the probable outcome of the present situation would be courses elective in their character. This experiment will probably be tried first in Harvard, and will give us an opportunity to judge of such a system as applied to stomatology, for I do not doubt that in these medical universities, as they will be called, stomatology will be one of the specialties taught. It is to be hoped that the experiment will be tried and prove successful, not only because it will give us a better class of men in dentistry but because it will be a stimulus to existing dental schools, which will be compelled to advance their courses to the standard of the elective course system, or sink to an acknowledged subordinate place and perhaps cease to exist. Allusions have been made to the ideal instructor as the one who endeavors to teach general principles as well as concrete facts. My observation is that the general instructor of to-day is the one who thoroughly drills men to pass examinations by hammering facts into them, and that it is the quiz master and not the professor who commands the largest following and most earnest attention.

One great trouble we have had and still have in advancing the course of instruction is the indifference of the student to scientific knowledge. Too many of them come to us with the idea that dentistry is simply a money-making trade, their highest aspiration being to learn to put in well-finished gold fillings; to such men dental science is superfluous and useless. I find that the most effectual stimulus to better scientific attainment on the part of students is the fact that in addition to the faculty examination they are compelled to go before state boards. This at the same time has forced upon the colleges more strict requirements and thus has accomplished a double good.

Dr. R. R. Andrews, Cambridge, Mass., has said that the elective system of the universities was just what was needed. As the university makes every man take certain studies to get his degree of A.M. or A.B., and then other studies in elective courses if he wants special degrees, so let the medical university take the medical course to get the M.D. degree and special courses for dentistry and other specialties. There is so much manipulative work in the study of general medicine that I can not conceive how a man could lose manipulative power by going through the medical course. If he has the intention from the first take up dentistry, his attention will be fixed upon dental work and his opportunities for it will be sufficient.

Dr. E. A. Bogue, New York—I hope that Dr. Litch will use all his persuasive powers of either tongue or pen to persuade the examining boards of the future to so examine the studnts turned out from our colleges as to determine not only what they know, but what they can do, and let their decision be based on the latter as much as on the former. Too often it appears as if the examination is simply to learn how many facts have been crowded into the student's head, not whether he can make any use of the fact. Dr. Kimball has said that the dentist owes a great debt to the community, not only the professional community, but the people at large among whom he practiced, also to his assistants, whom Dr. Kimball called his associates; and he carefully went into the *modus operandi* of choosing and training those assistants so as to first be assured it is a worthy man who is to succeed you in serving the public, and to see that as far as your effort will go, he shall be thoroughly equipped for the service. My old preceptor used to say that M.D. meant a miserable dentist. Dr. Varney, because he was a good dentist, became a good military surgeon.

Dr. Alice Steeves, Chicago—During my early experience I spent three years in hospital life, and the skill I obtained there in manipulating instruments has been of much benefit to me in dentistry. I think the dental and medical student should be educated in common.

DR. G. LENOX CURTIS, New York—We work all around the subject how to make dental students. My idea is first a good general education, then the medical education, then select those who have mechanical aptitude to study dentistry. Mechanical and literary ability do not go hand in hand as a rule, but we do not find men with marked mechanical aptitude among physicians. The student of the classics makes the best physician, the mechanic the best surgeon, and dentistry is surgery. Dr. Rhein says dentistry in America is deteriorating. That this seems so is because of the advance of dentistry in other countries, so our great knowledge does not seem so supreme as it did a few years ago. European dentists are being educated and they have good dental colleges now. So American dentists and American dental institutions do not stand out so clear against the horizon as they did fifteen years ago.

DR. M. L. RHEIN, New York—After listening to the admirable remarks of Dr. Hill, I wish to say that Dr. Hill's words were just what I would like to have said on the subject. I recognize my own inability to express my sentiments as well as Dr. Hill has. Some seem to have thought from my remarks that I feel that members of this Section have received slights in their connection with physicians, but I did not mean this. In my own case I have had no such experience. I was merely trying to draw the distinction which Dr. Hill had made so explicit. Dr. Marshall spoke of the estabishment of dental chairs in medical schools in Chicago. In my paper I noted the advance of the schools in the West over those in the East and limited my remarks to the conditions in the East. In this respect, we must recognize the superior advancement of the West. I have no knowledge at the present tme, after a great deal of inquiry, of any such education being given to medical undergraduates in eastern medical institutions and I specially limited my remarks in that respect to the East. The necessity for such a paper as mine was made much more marked by Dr. Marshall showing that this ground is covered in the city of Chicago, and is not covered in our eastern medical colleges.

DR. E. S. TALBOT, Chicago—I have been a disciple of Dr. Davis for the last three decades and have been looking forward to the advancement of dentistry and the amalgamation of the medical and dental professions. The fact that diseases of the mouth and of the general system are better understood is the underlying cause. Spencer says there is evolution in everything. There is evolution in dentistry, and those colleges and teachers who do not keep pace with this evolution must take a back seat. Dental colleges will have to take a step in advance and meet the issue. This law can not be overlooked. In this discussion, as always, the manipulative part of dentistry comes to the front. Is it possible that dentistry is based entirely upon plugging teeth? Do not diseases of the gums and of alveolar process constitute an important branch of dentistry? They are more prevalent than decay of the teeth and more to be dreaded. These diseases of the gums and alveolar process follow every disease of the human body, and are produced by changes in mode of living, changes in climate as witness our soldiers in Cuba and the Philippines and the workmen on the mountains in Switzerland, 2600 feet above the level of the sea. If this be true, the dentist must know about the diseases in the human system to practice successfully. Therefore, he must have a medical education. Dental colleges according to the present course can not include medical branches in their curriculum. Dr. Taft has informed me that the University of Michigan has increased the dental course of study to four years, of nine months each with an entrance qualification of a high school education. When all the colleges become able to not only give their students mechanical skill and manipulative ability, but also the necessary foundation knowledge of anatomy, pathology, physiology, chemistry, bacteriology, etc., their graduates will be thoroughly fitted to practice their specialty.

DR. A. E. BALDWIN, Chicago, introduced the following resolution; seconded by Dr. Curtis:

WHEREAS, It seems evident from the papers presented to our Section, and especially by the able paper of Dr. N. S. Davis that there should be a closer union between the medical profession and our specialty, and

WHEREAS, To bring this union closer it seems advisable that there should be established in all our medical colleges chairs on stomatology; therefore be it

Resolved, That we elect a committee of seven, consisting of the Chairman, Secretary, and Executive Committee of this Section with two others—of which committee our Chairman and Secretary shall be Chairman and Secretary respectively—to use all legitimate efforts to bring about the above results, and to work for the coeducation of all students in the foundation principles of medical education.

The Chairman appointed Drs. W. E. Walker, of Pass Christian, Miss., and James McManus, Hartford, Conn., on this committee.

SPECIAL ARTICLE.

RELATIONS OF PHARMACY TO THE MEDICAL PROFESSION.*

VII.

ARE TRADE-MARK NAMES NECESSARY.

The object of this series of articles is to try to reach a better understanding than now exists between medicine and pharmacy. That the former must depend on the latter to a large extent is acknowledged, and it is to the interest of both that present conditions be changed. The office of the physician is daily being encumbered with samples of all kinds and varieties of medical preparations, most of which are simply nostrums while some are of therapeutic value and a real advance from a pharmaceutic point of view. It is as much to the interest of honest scientific pharmacy as of medicine that the secret nostrums be banished, and these columns are open to the pharmacist who is willing to assist in the movement, or who may feel aggrieved at any statement made. For this reason space is gladly given to the following, especially as it gives a chance to discuss one phase of the subject.

NEW YORK, June 22, 1900.

To the Editor:—It is in the best interest of medicine that original investigation by competent persons should be encouraged. Very much of the advance in therapeutics is traceable to the work of those who have made a study of therapeutics, physiology, chemistry and pharmacy, and applied the knowledge gained to the perfection of such remedies as are decided improvements in medicine. Much of this kind of investigation has been carried on in the laboratories of those who have introduced these special preparations to the profession, and have relied for their reward upon the improved effect of their products in the hands of physicians.

There are many cultivated physicians who make a specialty of original research in pathology and diagnosis; these have contributed very largely to the great advance made in these studies of late years but unfortunately, the study of therapeutics has not made the same progress. I fear that the reason for this lies in the fact that the study of therapeutics and physiologic chemistry, as well as other branches of chemistry, have been too superficially taught.

If we stop for a moment to consider that a physician is constantly called upon to treat diseases, by chemical means, the gravity of the oversight will be apparent. The fact that the vital element in the organism is also a factor, while it does not nullify the argument, very greatly increases the complexity of the problem. Thus the lack of an equal knowledge of these two last links in the round of medical acquirement—therapeutics and chemistry—often handicaps the investigator in such a manner that he is unable to utilize his exhaustive studies in other directions, by his unfamiliarity with that essential and crowning knowledge which enables him to apply in a scientific manner, the indicated remedy to the morbid state which he has demonstrated.

It will thus be seen that many who have made therapeutics, physiology, chemistry and pharmacy a special study: have utilized such acquirements in improving the pharmaceutical condition of important remedies which are relied upon by the whole medical profession in the treatment of disease; have made such study common property with the profession at large by constant printed communications embodying the complete physiological arguments involved and affording the physician an opportunity to carefully weigh their value, to adopt or reject the statements made, are engaged in a work worthy of the most appreciative consideration of the medical profession, and should be encouraged to the utmost by them.

---

*The first of this series of articles appeared in THE JOURNAL of April 21.

As was before stated, such manufacturers have devoted themselves to the service of the medical profession; have given their entire time to this work for years; many of them have pursued strictly ethical means in introducing their specialties to physicians alone; have given the products introduced their correct pharmaceutical names; and have relied upon the use of their own names in connection with their preparations to induce physicians to prescribe the originators' products, as their sole protection against dishonest competition.

Failing to appreciate the character of the service rendered, or deceived into the belief that such preparations were no improvement over those made by any pharmacist or manufacturer, who, moved by cupidity and self-interest, and without the necessary knowledge to successfully imitate such specialties, has dispensed crude, imperfect substitutes in prescriptions, the physician has been largely imposed upon; the reward for important service in medicine has ben diverted from its rightful recipient, as the manufacturer finds that he is, to a large extent, booming the sale of vile imitations of his perfected products, for the effects of which he is held accountable in many cases; results promised are not secured; patients suffer.

Under these conditions, whenever such a manufacturer originates anything new, he is compelled in self-defense to give it a trade-mark name. This is not an attitude opposed to the physician; in fact it is in his best interest, as it renders him able, by ordering by this trade name, to secure the particular manufacturer's product he desires, and largely prevents the fraud perpetrated by many dishonest pharmacists. Such products are usually fully described by those who place them on the market, the active ingredients and proportions of the same are carefully given, and the physician knows what he is prescribing. There is another class of preparations which do not appeal to the confidence of cultivated physicians; mere mixtures of well-known and often-prescribed medicines, which involve no advancement in any direction, but are placed upon the market for the sole purpose of making money, and have no *raison d'etre* for their existence; these could be as well compounded by any pharmacist. They are on the market and are also given trade names; the law protects them in this privilege, they are vested rights and can not be interfered with. The remedy here lies with the physician himself: he should not prescribe them.

It has been proposed that manufacturers should patent their preparations, publish a complete working formula for their preparation, and enjoy (?) the exclusive sale of such for the period allowed—17 years. Experience has taught me that the only protection against the ravages of piratical manufacturing houses, who make a living by stealing the products of the brains of others and seek to monopolize the returns due the original investigator for his labor and expense in introduction, lies in withholding the manipulations employed, and taking out a trade-mark name.

Trade names have been adopted by nearly every legitimate manufacturer in the country; they have been driven to it by the dishonest practices of others. They are responsible for their existence. They are the ones who seek to abolish them. They interfere with their dishonest practices and they naturally wish them done away with. Very truly, yours,

R. W. Gardner.

To much of the foregoing hearty assent must be given. The conditions portrayed by Mr. Gardner are fairly in accord with other close and competent observers. Far from satisfactory, these conditions are shared by other branches of medicine in all that pertains to educational, professional and business relations. As has been pointed out time and again, it is the lack of thorough education and practical training in materia medica, chemistry and pharmacy, on the part of many medical graduates which is primarily responsible for their patronage of medicinal articles which are unworthy of support. This proposition is self-evident. The physician should be as competent to carefully discriminate in the selection of a remedy, or formulate a prescription for it, as he is to diagnose the disease. Lack of knowledge and practice in this respect places him at a disadvantage, weakens his self-reliance, impairs his usefulness. He will either fall into a "rut," believing it best to hold fast to that which has proved good, or cast about for every new-fangled remedy or combination that appears. In either event he is neither contributing to science nor doing his duty to his patrons.

But granted that all physicians had acquired a fairly comprehensive knowledge of materia medica and therapeutics, there yet remains the pharmacist. While there is a tendency to reversion to the older plan of the English apothecary in so far as physicians dispensing their own medicines, yet it is not believed that the separation of medicine from pharmacy, which has been going on so long, will continue.

The causes for this retrogression are well-known and need not be considered. But, especially engaged in the preparation, compounding and dispensing of medicine, the pharmacist should be regarded as indispensable and as such be entitled to a position in the great field of medicine. Unfortunately, the status of the pharmacist is not on the average any better than that of the physician on matters pertaining to pharmacy, so that it may be said that only a minority of either are qualified to fully perform their respective services, viz., prescribing and compounding *and dispensing. It is for these reasons that existing conditions* prevail and will continue as long as physicians will try anything and everything through their lack of information, or because they can not afford to trust pharmacists in preparation and compounding, owing to the unsatisfactory pharmaceutical education and training on the part of the latter.

The trade element in pharmacy is now rampant and is already bearing fruit, but there will be a better, more highly educated class of pharmacists who will deserve and will enjoy full medical confidence. In the meanwhile, there is need for patient and careful discrimination; unqualified condemnation will accomplish nothing. Every wholesale manufacturer naturally thinks that his article should have the preference. This is the case with Mr. Gardner. From an ethical standpoint, his manufactures deserve medical preference because they respond to ethical requirements. The preparations of hypophosphites are properly designated by pharmaceutic titles and his name is a guarantee of excellence. Probably every physician desiring to use hypophosphites knows of Gardner's and is far more likely to specify his make than if they were designated by some arbitrary fanciful title, such as for example: "Hyper-phos-ol," or "Phos-syr-ol," or some other hyperbolic combination or "*verbicide*."

It is not believed that the trade-names will afford protection against substitution, because any one who will substitute one brand of an article for another without the prescriber's consent, would not hesitate to indulge in the same practice with trade-name articles. On the other hand, it would alienate the favor and preference of many medical men who are opposed to trade-names on ethical and other grounds, not the least of which is the taxing of their memories with new and meaningless names. The multiplication of these coined names has been so great as to prove not only confusing but even dangerous to prescribers, owing to their often great similarity. Besides such names have especial fascination and charm for the cultivated laity who are constantly on the lookout for new remedies for self-medication and subsequent exploitation to their friends and relatives. Since Mr. Gardner has pursued the laudable course of addressing himself to the medical profession exclusively, he certainly would not favor such method.

The criticism concerning the exploitation of "mere mixtures" which have no "*raison d'etre*," but "to make money" for somebody and that "these could be well compounded by any pharmacist," is well taken. But here is where Mr. Gardner treads on dangerous ground. If he had been more explicit as to what are defined as "mere mixtures" he would have contributed greatly to the solution of this question. While the articles of his manufacture are official in the pharmacopeia and any qualified pharmacist should be able to make similar preparations, as has already been observed in these articles, their satisfactory preparation as a class involves certain conditions not always met by the average druggist. But would any other manufacturer agree that his articles were "mere mixtures" and had no "*raison d'etre?*" Certainly not.

It was contended in one of the earlier articles of this series that originality or invention was entitled to the protection that a patent affords, but such protection should not extend through trade-mark to the name of the article, but only to the proper name or symbolic devices. Our correspondent's opinion that the suppression of the manipulations and employment of trade-names is the only protection is antagonistic to the basic principles of medicine and pharmacy, and contrary to the course pursued by him some years ago. When advocating that the most complete information be furnished pharmacists, he himself contributed a very elaborate and excellent collection of formulas with full working processes for these very preparations. This information entered into the pharmaceutical literature and some of the preparations were incorporated in the pharmacopeia. This was the ethical plan. It is still followed by some manufacturers; why should it not be by all? Upon it rests all progress. The leading reliable manufacturing pharmacists, as for instance, Squibb, Wyeth, Sharp & Dohme, Parke, Davis & Co., and others, do not resort to trade-mark, their own names being sufficient. Those who do are chiefly the promoters and outsiders, who, through the use of trade-names, seek to rob the legitimate manufacturers of their just returns. As to who are responsible for the attempt to abolish trade-names, the charge of esoteric motives is gratuitous. The two most representative bodies concerned, the AMERICAN MEDICAL ASSOCIATION and the American Pharmaceutical Association are committed to the principle.

It is believed that Mr. Gardner and all reputable manufacturing pharmacists appreciate these facts: 1. The physician is entitled to and demands the fullest information concerning the products he is asked to prescribe and use; 2, in order to insure their identity and that they may gain a place in medical literature, all medicinal preparations should be designated by pharmaceutically descriptive titles and not by mysterious names, accompanied by befogging literature; and, 3, the manufacturer who adopts the above two propositions and carries them out honestly and honorably will add prestige to his products, dignity and reputation to his name, which, on the label of a bottle, would be worth more than any copyrighted proprietary title.

Therapeutics.

Treatment of Croupous Pneumonia.

At the Eighteenth Congress for Internal Medicine, held recently at Wiesbaden, Pel, of Amsterdam (*Berliner Klinische Wochenschrift*, 1900, No. 18, p. 398), pointed out that in most cases of croupous pneumonia, Nature unaided is capable of effecting a cure through the compensatory powers of the body for neutralizing pathologic processes. The attacked organism possesses various protective influences through which it opposes the morbid process and neutralizes it toxic effects. The important part played by leucocytes and fibrin is indicated by the hyperleucocytosis, and the hyperfibrinosis of the blood, frequently present. Possibly, elevation of temperature is an adjuvant of these two factors. The fate of the pneumonic patient is thus determined, not alone by the conditions present in the lungs, but also by those in the fluids of the body. The constitution or the individuality of the patient, which determines the intensity of antitoxin-formation, as well as the strength of the protective agents, is of decisive importance. In cases of pneumonia that pursue a less favorable course, certain constitutional anomalies influence the abnormal irregular course. The danger to life is greater in patients with emphysema, bronchitis. nephritis, diabetes. in the aged and the reduced, in the neurotic, and especially in the alcoholic, when attacked by pneumonia, than in the healthy. Objective investigation has shown that there is no single remedy by means of which it is possible to shorten or to influence favorably the pneumonic process. The value of serumtherapy in this connection is as yet undecided. Some of the remedies proposed as specifics may, however, be employed for the relief of symptoms. Thus, venesection may be indicated in the presence of severe dyspnea, cyanosis and feeble pulse, and also of beginning pulmonary edema, and it may be of life-saving value. Digitalis in small doses may act as a cardiac tonic, but it is indicated only when pneumonia occurs in a patient with disease of the heart, and cardiac weakness appears, or cardiac insufficiency becomes a prominent feature. Large doses, however, are not to be recommended. The less the physician interferes in cases of pneumonia of regular course, the greater is the probability of successful termination. This does not, however, mean that the physician should do nothing. There yet remain the institution of an intelligent hygiene, of careful nursing, and of proper diet, and the mitigation of the most distressing symptoms, in order that the conditions of natural recovery may be rendered more favorable. Nothing should be considered too slight or too insignificant for consideration. For the distressing cough and embarrassed expectoration, the powder of ipecac and opium may be administered; for the severe pain in the side, if necessary, subcutaneous injection of small doses of morphin; and, later, for the embarrassed expectoration, an expectorant. Irregular and atypical cases require, on the whole, a stimulating course of treatment. In such cases there is danger from heart-failure. While premature and excessive stimulation may do harm, the opportune employment of such an agency may be the means of saving life. Alcohol occupies a place in this connection, exerting a stimulating and invigorating influence. Excess, however, is to be avoided, especially in the young. Camphor is the most reliable restorative, given at first in small doses, and, when the danger is great, in large doses, and especially subcutaneously in combination with ether. It may often be the means of saving life. Methodical sponging of the skin is agreeable to the patient, and exerts a favorable influence. The elevation of temperature does not require the use of antipyretics, and is unattended with danger. It is probable that the fever is a conservative and a useful reaction on the part of the infected organism. Prophylactic measures are, however, indicated. The constitution of the patient should, as far as possible, be preserved intact, in order that, should he be attacked by pneumonia, the natural protective influences may become operative in full vigor. The principal indication here is to avoid excesses and over-exertion in every direction, even during health.

Treatment of Tubercular Cystitis.

The *Clinica Moderna* gives the following:

In the first stage—viz., before surgical intervention is called for—it is requisite to combat the purulence of the urine and the pains. To that end one of the following formulæ may be used:

℞. Codein sulphatis ....gr. ivss
Salol ....gr. xc

M. divide into twenty powders. Sig. One powder to be taken after each meal.

Or:

℞. Cocain hydrochlorit
Ext. cannabis indicæ, āā..............gr. ivss
Guaiacol carbonatis.....................gr. xc

M. ft. pl. No. xx. Sig. One pill to be taken after every meal.

Against fermentation of the urine urotropin may be given in 4½-gr. doses four times a day.

Lactic Acid in Gynecology.

Dalche has found lactic acid a natural antiseptic for the vaginal cavity. In 3 per cent. solution it destroys the bad odor and greenish-yellow color of leucorrhea and lessens the quantity of the discharge. It causes curative desquamation when applied in half-strength in endometritis and endocervitis. It causes no danger.

The author, after douching with lactic-acid solution 1:35, puts in tampons of 1:33 in glycerin every eight days, with daily hot-water douches in the interim.—*Merck's Archives.*

Bed Sores.

℞. Argenti nitratis..........................gr. xl
Aquæ dest. ....fl℥ii

M. Sig. Paint red and tender spot daily.

Indications: To be employed over red and sore spots that threaten to break. Also employed if surface ulcerates.

℞. Hydrarg. perchlor.........................gr. ii
Spir. rect.................................fl℥i

M. Sig. Use locally.—*Erichsen.*

℞. Alumen
Sodii chloridi, āā..............................℥ss
Aquæ
Alcoholis, āā...................................Oi

M. Sig. For local use, twice daily.—*Forbes: Dominion Med. Mon.*

Agalactia.

℞. Strychninæ sulphatis ....gr. i
Pilocarpinæ hydrochloratis................gr. i
Sacchari lactis..............................ʒiss
Alcohol, q. s.

M. et ft. tabellæ triturationes No. lx. Sig. One tablet every four hours.

Indications: The various malt extracts, with or without cod-liver oil, are available adjuvants. Massage of the breasts is also recommended.

℞. Ext. ergotæ
Ext. nucis vomicæ, āā.....................gr. vi
Quininæ hydrochloratis..................gr. xxiv

M. et ft. pl. No. xxiv. Sig. One pill every six hours.

Indication: Use in anemic subjects.

℞. Ext. pilocarpi fl.........................fl℥ii

M. Sig. Teaspoonful two or three times a day.—*Bartholow: Dominion Med. Mon.*

Spermatorrhea.

In spermatorrhea and anaphrodisia of neurasthenia, Bozzolo and Mangianti advise:

℞. Cornutin citratis...........................gr. ss
Cretæ preparatæ...... ....gr. xlv
Gum arabic........ ....gr. xxxiss

M. ft pil. No. xx. Sig. From two to four pills to be taken daily.—*La Medicine Mod.*

Bleeding Gums.

After the extraction of teeth, Vian recommends the following as an efficient styptic to check the bleeding:

℞. Chloroformi ....ʒi
Acidi tannici
Menthol, āā.....................................ʒss
Tinct. krameriæ...............................ʒi
Aquæ dest., q. s. ad.........................Oi

—*Louisville Med. Mon.*

Erysipelas.

℞. Acidi carbolici
Tinct. iodin
Spiriti rect., āā..............................℥iii
Ol. turpentini..................................ʒx
Glycerini ....℥iii

M. The site of the disease is to be painted with this mixture every two hours and then covered with antiseptic gauze.

℞. Ichthyol ....ʒx
Petrolatum ....ʒviii
Lanolin ....ʒxv

M. To be applied locally.—*Louisville Med. Mon.*

Alopecia.

℞. Resorcini ....ʒii
Acidi salicylici........... ....gr. xxx
Olei ricini......................................flʒi
Spirits rectified..............................flʒvi
Olei bergamot.................................flʒi

M. Rub well into the scalp every night.

When greater stimulation is desired, use:

℞. Mercuric chlorid.........................gr. xii
Betanaphthol ....gr. xl
Castor-oil ....flʒii
Spirits rectified
Bay rum, āā.....................................fl℥iii

—*Schamberg: Polyclinic.*

Warts.

Louvel-Dulongpre (*Med. Neuigkeiten*) advocates the following painless treatment, which also has the advantage of leaving no cicatrix. A concentrated solution of potassium bichromate in boiling water is prepared by gradually adding to the latter enough of salt to make a saturated solution. On cooling, a certain quantity of the salt will again be precipitated. The supernatant fluid is to be applied once a day by means of a brush.

Cardiac Stimulation for a Child.

℞. Spir. etheris comp....................m. lxxx
Tinct. nucis vomicæ........................m. xl
Tinct. lavandulæ comp..................m. lxxx
Aquæ cari, q. s. ad.........................℥iv

M. Sig. One tablespoonful every four hours to a child of 8 to 12 years.—*Ashby: Med. Record*

Asthma.

℞. Ext. euphorbiæ piluliferæ fl.................fl℥i

M. Sig. Thirty to sixty drops, as required. —*Payne.*

℞. Pulv. stramonii fol.
Pulv. belladonnæ fol., āā.......................℥i
Pulv. potass. nit................................ʒiss
Pulv opii...gr. xv

M. Sig. Burn a little and inhale the fumes.

℞. Potass. iodid......... ....ʒviss
Tinct. lobeliæ...................................flʒviiss
Aquæ dest.......................................flʒxvss

M. Sig. From a teaspoonful to a tablespoonful in a glass of beer before meals—*Dujardin-Beaumetz: Dominion Med. Mon.*

Bites of Insects, Etc.

℞. Liq. ammon.
Collodii, āā.. ....gtt. xc
Acid. *salicyl*...................................gr. iii

M. Sig. Apply a drop upon each bite.

℞. Naphthalin
Vaselin, āā q. s. ad saturated.

M. Sig. Rub in a few drops every four hours.—*Louisville Med. Mon.*

Sodium Benzonte in La Grippe.

According to the *Medical News,* no drug has given more favorable results in the treatment of la grippe than benzoate of soda. It may be given in capsule or powder form, the usual dose being ten grains three or four times a day. When muscular symptoms are pronounced the following combination acts admirably:

℞. Sodii benzoatis...............................ʒii
Salol ....ʒi
Phenacetin ....gr. xxxvi

M. et ft. chart No. xii. Sig. One powder every four hours.

Belladonna in Bronchopneumonia.

A. H. Frere says that the great value of belladonna in asthma and whooping-cough is well recognized and when we come to consider the main actions of this drug on the nervous and vascular systems, we find there are many reasons why belladonna should prove of value in bronchopneumonia. As an antispasmodic; as a stimulant to the cardiac muscles; as a stimulant to the vasomotor and respiratory centers; and lastly, as diminishing secretion, it must tend to relax the tubes, to obviate the stasis of the vessels around the bronchi, and facilitate the breathing. He says that he has been accustomed to employ iron in these cases with great benefit, having regard to the fact that this remedy increases the number of blood-corpuscles and the oxygen-carrying power of the same.—*Merck's Archives.*

Abortion (To Prevent).

℞. Tinct. opii deodorati.......................flʒii
Chloralis ....ʒii
Ext. hyoscyami fl.............................flʒi
Syr. acaciæ ....flʒiv
Ext. *viburni prunifolii, q. s. ad*..............fl℥iii

M. Sig. One or two teaspoonfuls every hour or two until moderate somnolence.

Indications: In threatened abortion, give in sufficient doses to secure the continuous moderate effects of opium and chloral. Complete rest in bed, light diet, and daily moderate evacuation of bowel.

℞. Ext. opii
Ext. hyoscyami alcoholici, āā............gr. iii
Ol. theobromatis, q. s.

M. et ft. suppositoria No. vi. Sig. One by bowel as required.

Indications: In threatened abortion employ every hour or two until somnolence. Bowels to be moved daily by mild laxative of cascara or saline or by an enema.

℞. Hydrargyri iodid. avi........................gr. x
Sacchari lactis, q. s.

M. et ft. tabellæ No. xl. Sig. One after meals.

Indications: In habitual abortion due to syphilis, increase dose until slight soreness of gums or tendency to diarrhea, then reduce to tonic dose. Continue during pregnancy.—*Dominion Med. Mon.*

Infantile Constipation.

Dr. L. Emmett Holt has said that the conditions found in young children were such as to make the treatment of constipation in these little patients proportionately easy and satisfactory. He always insisted on a careful scrutiny of the whole of the child's daily life. The nurse was often to blame for the constipation in the infant. In infants under six months of age constipation was often due to the use of modified milk in too small percentages, so that too little residue was left. Under such circumstances the indication was to increase the total solids. The bad cases of chronic constipation in children of 5 or 6 years of age that he had seen had been almost without exception in children who were exceedingly healthy and robust. He could heartily recommend cascara as being probably the most valuable drug in the treatment of cases in which there was loss of expulsive power. Still better than drugs, in his opinion, were suppositories.—*Medical Record.*

Vaginismus.

Dr. Touvenaint (*New Yorker Med. Monatschrift*) advises the following:

℞. Stront. bromid.
Potass. bromid.
Ammon. bromid., āā......................℥1¼
Aquæ dest.................................℥8
M. Sig. Tablespoonful twice a day.
Or:
R. Zinci valerianat........................gr. 5/6
Quinin. valerianat.................. ...gr. 1½
Ext. opii.
Ext. belladonnæ, āā....................gr. 1/6
M. Ft pil. No. 1. Sig. From 3 to 6 pills daily.
Locally:
℞. Ext. krameriæ..........................gr. 1½
Morphin. hydrochlor....................gr. 1/3
Ol. theobrom..............................ʒi
Ft. suppositoria vaginal.
Or:
℞. Cocain hydrochlor........................gr. 3
Ext. belladonnæ........................gr. 1½
Strontii bromid..........................gr. 4
Ol. theobrom..............................ʒ1¼
M. Ft. suppos. vaginal.—*Ex.*

Salol and Cocain in Burns.

Dr. Capitan (*Cronica Medica*) asserts that the following ointment suppresses pain and suppuration in burns and promotes healing:

℞. Salol ....gr. 120
Cocain hydrochlorid......................gr. 7½
Vaselin ....gr. 900

Dr. Capitan uses in addition compresses moistened with solutions of corrosive sublimate in water of .25 to .5 per cent. strength, or of borated water, 1:50.

Medicolegal.

Separation Agreements on Account of Health.—While much controversy has arisen as to the validity of separation agreements, and although judges have frequently and in strong language deprecated the cause and effect of them, and condemned agreements by which they were accomplished, nevertheless, the Supreme Court of Kansas declares, in King vs. Molohan, that it may be regarded as settled law in England and this country that a valid agreement may be made for an immediate separation between husband and wife, where the conduct of one is such as to render a separation necessary for the health and happiness of the other, or when their relations are such as to make separation inevitable.

Cognizance Taken of Mortality Tables.—The Appellate Court of Indiana states, in Chicago, Indianapolis & Louisville Railway Company vs. Neff, that the court will take judicial knowledge of the United States mortality tables, and of other standard tables of the same character., It also says that where a witness has shown his competency to testify as to the expectancy of a life the proper course is to ask him to state the expectancy and let him refer to the tables in order to refresh his memory, and not to ask him what is the expectancy of the life as shown by the tables.

What Constitutes "Sound Health."—The Supreme Court of Ohio holds, in Metropolitan Life Insurance Company vs. Howle, that, in life insurance, "sound health" means that state of health which is free from any disease or ailment that seriously affects the general healthfulness of the system, not a mere indisposition. And it pronounces unobjectionable the following charge to the jury: "Sound health," as used with reference to life insurance, means that state of health, free from any disease or ailment, that affects the general soundness and healthfulness of the system seriously, and not a mere indisposition, which does not tend to weaken or undermine the constitution of the assured. The word "serious" is not generally used to signify a dangerous condition, but rather a grave or a weighty trouble.

Fright from Witnessing Another's Peril.—The Appellate Court of Indiana thinks it remarkable that no precedent was cited to it, and that it was itself unable to find any, of an action having been successfully maintained similar to the case before it of the Cleveland, Cincinnati, Chicago & St. Louis Railway Company vs. Stewart wherein the latter-named party sought. and recovered a judgment for, damages for "nervous prostration" caused by fright from seeing her daughter in peril attributed to the negligence of the railway company. In other words, it says that it was not cited, by the learned counsel engaged, to any case, nor has it been able, after the most diligent research, to find any case, holding that fright occasioned by imminent danger to one person can be made the basis of an action for damages by another. And, in the face of the authorities, it declares that it is not willing to establish such a precedent by an affirmance of the judgment to that effect in this case. Witnessing an injury or a threatened injury to another, even though it causes fright, the court goes on to say, is not in itself an injury to the person witnessing it. There must be some direct physical connection between the cause and effect. Hence, the fact that one is frightened by observing another in danger, and that such fright brings on nervous prostration, gives no cause for action to the former. Nervous prostration, it also considers, is largely a mental, and not a physical, condition.

Board of Health as Part of City Government.—The Board of Health for the City of New Orleans owes its origin to the provision in the act of 1898 making it incumbent upon the council or legislative body of each and every incorporated municipal corporation of the state to establish and organize a town or city board of health. It is a part of the city government, the Supreme Court of Louisiana holds, in State, on relation of the board, vs. Common Council. It has not had conferred upon it, by the general assembly, an unrestricted power, for example, of determining how much money should be appropriated for its purposes by the common council in any given year. Of course. having been entrusted with the special and important duty of guarding the public health, it can not but keenly appreciate a situation which might leave it crippled in its action. But, the court insists, there is no more ground for independent action on its part in determining the amount of money it shall have to expend, than there would be for the police, or any other department of the city government. The intention of the general assembly was that the board of health and the council should act together for the attainment of any object in which they have a common interest. The city is not unlimited in its power to raise funds; there are other important objects besides the preservation of the public health to be attained, and, where the constitution has ordained, the citizen has but to obey, and to discharge his duty as best he may, with the limited instrumentalities placed in his hands. So, the court holds, if the appropriation for the board of health be too small it will have to diminish its force and curtail its expenses. The court has no right to assume that the common council is any less solicitous for the health of the city than the board itself, and it has no authority to order the council to enlarge the amount placed by it on its budget for the prospective expenditures of the city board of health.

Legal Compensation for Suffering and Death.—According to the Supreme Court of Arkansas, in assessing damages for wrongs causing death, the law does not undertake to find a sum equal to the value of life to the deceased or for which the person killed would have voluntarily suffered death. That would be impracticable; for to most persons life is a priceless gift, which would not be surrendered for the value of an entire railroad paid to their estate. Nor, in allowing a recovery for pain and suffering, does it aim to fix a sum that would lead one willingly to endure such pain; for few would consent to have a leg crushed off, and bear the loss, for many times the sums allowed. The injury being irreparable and already suffered, the jury, after hearing the evidence, are allowed to assess a sum which, in their judgment, they deem a reasonable compensation; having regard for the severity and duration of the pain and suffering. They are given great latitude in such cases, for courts do not undertake to measure pain and suffering; but their judgment is not altogether uncontrolled, and, when such questions are brought before the judge on motion for new trial, in determining whether the proper bounds have been exceeded, he must, to a large extent, be governed by the practice of courts in such cases as shown in the decisions. Now, all of these decisions, so far as the court knows, hold that in cases of instantaneous death, nothing can be recovered for pain and suffering. And the same rule, it says, is applied when, though life remains a few moments, unconsciousness instantly follows the injury; for in such a case no conscious suffering is shown. The burden of proof is on the plaintiff to show that the deceased, as a result of the injury, underwent conscious pain and suffering. And an administrator can recover only such an amount as the deceased might have recovered had he been miraculously restored to life and health at the moment of his death. In view of all of which, the court holds, in the case of the St. Louis, Iron Mountain & Southern Railway Company vs. Dawson, that where a child between 6 and 7 years of age was run over and so injured that she died in a moment or so, even if the evidence justified more than nominal damages, an award of $4000 to her administrator for her pain and suffering must be considered excessive.

Night Medical Service.—The charter of the new City of New York provides for what is called the night medical service. Any physician may apply to the police captain of the police precinct in which he has his office to be registered as a physician to be called upon by the police to do such medical service; and upon the Registrar of Vital Statistics certifying that he is in good and regular standing in his profession he shall be so registered. On the application of any person residing within such precinct for medical attendance between 10 o'clock at night and 7 o'clock the next morning, the police officer in charge at the precinct station-house must detail an officer to call upon a physician so registered and conduct him to the residence of the patient. After the medical service is performed, the accompanying officer has to give a certificate to that effect to the physician, stating the name and address of the patient, and that the physician is entitled to $3 for such service. Such physician must then request payment thereof of the patient, and in default of such payment the captain of the precinct has to indorse such certificate; "and thus indorsed it shall be the duty of the cashier of the department of health to pay at sight the fee aforesaid." And the charter is mandatory that the Board of Estimate and Apportionment and the municipal assembly shall make an appropriation for such purpose each year, and put it in the tax levy; the sum not to exceeed $3000, unless otherwise provided by said board and the municipal assembly. But notwithstanding this, it was made a defense, in the case of Dixon vs. the City of New York, that when the night medical services which it was here sought to recover for under these provisions were rendered, there was no money appropriated to pay for such night medical service. This defense, however, Mr. Justice Gaynor would not accept. He holds, at a trial term of the Supreme Court of New York, that the appropriation for this service is one which said board and municipal assembly are required to make, and that they can not, by failing to make it, prevent the purposes of these provisions of the city charter from being carried out, and can not prevent such expenses being incurred, any more than they can in a similar way prevent the mayor and corporation counsel from collecting their salaries. They are empowered to fix a limit which the expense of the night medical service shall not exceed. This they may do in good faith, but they may not refuse to make an appropriation for it. And the plaintiff, it is held, had a right to presume that they had obeyed the mandate of the statute, and was entitled to a judgment.

Privilege in Case of Infant Patients.—Infants and others laboring under a disability, the appellate term of the Supreme Court of New York holds, in Corey vs. Bolton, are covered by the word "patient," where a physician or surgeon is prohibited by statute from disclosing any information which he has acquired in attending a patient, unless there be an express waiver upon the trial or examination by the patient. Such a statute, it maintains, should have a broad and liberal construction, to carry out its policy, and, so construed, would cover all patients, regardless of their legal status. Certainly one who has been a patient prior to a disability does not become any the less a patient because of the disability. This much being settled, the court takes up the question of waiver in the case of an infant patient. A construction that the waiver can not be made by persons under a disability, it says would suggest that the statute was rather for the protection of those opposed to these persons, than in their favor. Consequently, it does not put that construction upon it. It holds, as the reasonable construction to be put upon the law, and it is not only, as before stated, includes in the word "patient" all persons, regardless of disability, but, besides giving them the privilege of the privacy, gives them the right to waive it. But how, for example, can an infant waive the privilege? A waiver is an intentional relinquishment of a known right, and must be by one capable of binding himself, and so can not be made by an infant personally, for he has a right to be protected against his own imprudence. It is not to be assumed, the court goes on to say, that the statute contemplated that persons under a disability should waive personally, annd therefore some representative must have been in the minds of the lawmakers as authorized to make the waiver. With respect to infant patients who are not parties to an action at the trial of which the waiver is sought to be made, the guardian of the person would seem to be the most appropriate person to make the waiver; for to this guardian are confided the rights which pertain to the person of the infant, and the right of waiver given by the statute has been held to be one which pertains to the person and character of the patient, and not such as belongs to a representative of property rights. The guardian should, however, never be permitted to make a waiver prejudicial to the interests of his ward; but it does not seem that it is necessary that it should affirmatively appear, upon a waiver by such a guardian, that the waiver is a benefit to the infant. The guardian may be permitted to exercise his own judgment with respect to the question of prejudice to the child, and unless called upon to do so, no showing need be made by him primarily in order to be able to make the waiver. Of course, the court says, the ward would not be so bound by a guardian's waiver that he could not at any later time assert his privilege, if it appeared that the waiver had been to his prejudice; and so, as to him, the rule that the privilege, if once waived, is waived forever, does not apply, under all circumstances. Nor has the court been able to discover any sufficient reason for confining an infant's right to waive to any particular action, or for holding that the infant's interest must be so involved that the waiver will be to his pecuniary advantage. It may be an infant's interest, it thinks, beyond any requirement for the privacy allowed by the statute, to waive, that the ends of justice be furthered. The parents being the natural guardians, and so the guardians of the person, the court holds, can make the waiver. Whether a guardian *ad litem*, or one appointed for the purposes of a suit, can, in a proper case, make the waiver, the court passes with the remark that it was not necessary in this case to determine.

THE JOURNAL OF THE
AMERICAN MEDICAL ASSOCIATION.
61 MARKET STREET, - CHICAGO.

SATURDAY, JULY 7, 1900.

HEALTH AND SUMMER RESORTS.

So many people now leave city homes for a summer sojourn in the country that the question of health during the change of residence has become very important. At most of the summering places public spirit and the feeling that it is a paying investment lead to the taking of sanitary precautions that will insure as far as possible the health of summer visitors. Each year sees such an addition to the number of those who leave town during the hot months, that the enforcement of sanitary regulations may not keep pace with the increasing crowd of visitors. The present summer, coming as it does in the midst of a period of almost unexampled prosperity, is apt to test the capacity of most summer resorts to its utmost. When the number of visitors exceeds expectations, ordinary sanitary precautions prove unavailing. In Germany stringent legal regulations give more or less assurance of the enforcement of thorough sanitary measures. In default of regulation in America, physicians are called upon to know the details of the sanitation of places to which families under their care go.

The most important matter is the water-supply. The best practical index of its wholesomeness is the number of cases of typhoid that have occurred in a town during the spring and preceding fall. This is, as a rule, easy to ascertain. No typhoid means pure water. There is one exception to the rule. If there has been an undue proportion of gastro-intestinal affections, and especially if these have been dysenteric in character, the non-occurrence of typhoid may mean only the absence of specific infectious material. Water may be contaminated by sewage, but there being no typhoid in the neighborhood, cases of the disease are not produced. The importance of a single case will almost surely lead to an epidemic.

Next to the water-supply in its sanitary importance comes the milk-supply. As milk forms such a large part of the diet of children it can scarcely be considered second in import even to water. Children especially are sent to the country for the summer, and their lack of resistive vitality during the developmental period renders them especially liable to infections. It is a common fallacy that away from cities milk must be fresh and good. As a matter of fact the precautions taken to preserve city milk often assure a much better article than is obtained by those living in the country. Ice is a most important factor in the preservation of milk. It inhibits micro-organismal development. It is used liberally for city milk and, even though the milk is distributed from twelve to fifteen hours after milking, it contains very few more bacteria than it did originally. In the country the use of ice is more neglected. It is important then to know the source of the milk that is used, and to be assured of its careful preservation on ice until the time not only of its distribution but of its consumption.

There are other dangers, but of secondary importance. Of late years botulism—poisoning by spoiled meat—has come to occupy a much larger place in medicine than heretofore. Its symptoms are due to the presence of one or more specific microbes, which have recently been isolated and studied. They occur in sufficient numbers to be virulent, especially in canned meats that have been left open for some time before being consumed. The bacillus botulinus, as it is called, multiplies very rapidly in albuminous substances that have been kept from contact with oxygen for some time and then are freely exposed to the air. In our time the use of preserved meats has become so general during the summer that a word of warning in this matter is important.

"WHAT KNOWLEDGE IS OF MOST WORTH?"

In an article entitled "A Consideration of Herbert Spencer's Essay on Education," David Starr Jordan,[1] president of Leland Stanford University, points out that Spencer placed first on the list in importance among the leading kinds of activity constituting human life, "those activities which directly minister to self-preservation," and next in order those that indirectly operate toward the same end. Probably no one will deny the paramount importance of perfect physical and mental health. Ill health, whatever its cause, "deducts more from complete living than anything else," and shortens by at least one-half the possible duration of life. Hence Spencer concludes "that, as vigorous health and its accompanying high spirits are larger elements of happiness than any other thing whatsoever, the teaching how to maintain them is a teaching that should yield in moment to no other whatever." And Jordan goes on to point out that it is not merely hygienic rules that should be inculcated, but such a knowledge of physiology that the student may formulate "his own rules of health for himself." This does not mean, however, "every man his own physician," but that every educated person should have sufficient scientific knowledge to be able to tell a scientific physician from a quack. No physician but will assent to the statement that "because of the fundamental value to the individual, hygiene, with the laws and facts of physiology and biology, should have a leading part in any well-ordered scheme of education."

It is a healthy sign of the times to find that prominent educators place a true knowledge of the laws of health first in their answer to the question—"What knowledge is of most worth?" But how many of our academies, colleges, and universities are fully prepared to give their students the knowledge that is worth most? Probably not many would be able to met the requirements that scientifically-educated physicians might wish to exact.

---

[1] The Cosmopolitan, June, 1900.

In fact, perhaps as yet not a single course of studies has been arranged with the object of meeting requirements of this character as the primary object in view. And yet our educational institutions of to-day are far better prepared to meet criticisms along these lines than those in England were when Spencer startled the educational world with his question, "What knowledge is of most worth?"

The field is a large one, and at this time and in this place it may be sufficient to indicate that the prominence given to natural sciences in our better schools, and to physical culture, makes for common-sense as regards matters of health. It is not so much sciences as wisdom that is necesary in order to understand and to obey the laws of physical well-being, and the day is still distant when there shall be "no medical fraud so shameless that educated men will not give it their certificate."

CHRONIC, HYPERPLASTIC TUBERCULOSIS OF CECUM.

There occurs a form of localized, circumscribed tuberculosis of the bowel that may be successfully treated by operation. This is the hyperplastic form of tuberculosis, the counterpart of which is seen also in other tissues, such as the skin, larynx and lymphatic glands. The thickening of the intestine may be so marked as to produce a swelling grossly a carcinoma. As pointed out by Crowder[1] in his study of two cases of this affection, in one of which a carcinoma of the cecum coexisted, this form of intestinal tuberculosis is most frequent in the region of the cecum. Its history in pathology is brief, having been first described in 1890 by Durante; since then the subject has been discussed extensively by German and French surgeons, but no general summary of the knowledge of the condition appeared in the English language before Crowder took it up and gave it a thorough consideration. Indeed, the text-books just now are beginning merely to mention it. This is the reason we call especial attention to this form of intestinal tuberculosis.

The first case recorded by Crowder occurred in a colored girl of 14; a tumor of the cecum was removed by resection; end-to-end anastomosis was practiced, and recovery ensued. The patient gave a history of recurring cramp-like pains in the abdomen for about eight months; after a time transitory swellings appeared, and a mass as large as a lemon was felt in the cecal region. There was no evidence of any tuberculosis elsewhere in the body.

The second case occurred in a woman of 54; here there was no operation, and the hyperplastic cecal tuberculosis was associated with carcinoma, springing from the margin of an old tuberculous ulcer. There was an inguinal fistula of long standing. Crowder found but one previous instance of this association in the cecum, the case of Salzer from Billroth's clinic. In Crowder's second case there was a chronic tuberculosis of the lungs.

The great inelastic thickening of the cecal wall observed in these two cases, as well as in others in general, is due to overgrowth of the fibrous and muscular structures and to the formation of a non-degenerated, persistent tuberculous granulation tissue in the submucous coat especially. There is almost always stricture at or near the ileocecal valve. Constrictions also occur in the ileum due to similar conditions. In addition to ulceration, the mucous membrane presents quite constant and characteristic papillomatous outgrowths of varying size and form. Tuberculosis of the retrocecal glands is frequent. Tuberculous peritonitis rarely develops. As stated, the tuberculous tissue in the cecum has but little tendency to disintegration.

Of 84 patients, 40 were male, 44 female; the majority were between 20 and 40 years of age. As regards the genesis of this interesting form of tuberculosis, it is noteworthy that there is frequently found in these cases a latent, active or inactive pulmonary tuberculosis. In destructive tuberculosis of the intestine, on the other hand, there is commonly destructive, extensive involvement of the lungs. This indicates that intestinal tuberculosis, almost without exception secondary, takes now a destructive form, now a hyperplastic and chronic form, according as the general resistance of the organism varies. At the same time the character and the number of bacilli present undoubtedly also have something to do with determining the nature of the lesions.

In conclusion, it is to be noted that the hyperplastic, localized tuberculosis, referred to in the foregoing, hereafter must be considered carefully in the differential diagnosis of intestinal new growths and that it is a form of intestinal tuberculosis amenable to surgical treatment, as shown in the first case described by Crowder and in the cases recorded by Lennander and Krogius.[2]

MONOGAMY AND LONGEVITY.

An English physician, Dr. Harry Campbell (*The Lancet*, June 9), insists on the importance of cultivating a high racial standard to prevent racial deterioration and claims that this can not be done alone by sanitation and prevention of disease. There must be also a vigorous weeding out of the unfit if we are to insure a healthy race, and ignoring of this fact is one of the most grievous fallacies. The elimination of the unfit in the natural way acts beneficially by limiting their production of offspring repeating their own defects. He lays it down as an axiom that all non-accidental deaths occurring before the close of the reproductive period are, racially considered, deaths of the unfit, therefore, in a racial point of view, beneficial. This effect is greatest when death occurs before the procreative period, and ceases altogether when it takes place after its close. He also assumes that it is in the order of nature for all organisms to die soon after the cessation of their reproductive activity and that this is true of men applying these ideas to the question of human longevity. Dr. Campbell argues that the procreative period of the male of our species is certainly prolonged beyond the Psalmist's three score years and ten, and that we owe to this the ability of any of us to exceed that limit in our lives. "Had no man," he says, "during the last 100,000 years got offspring after the age of 50, we should all probaby tend to die of old age about this time."

---

[1] Am. Jour. of Med. Sci., 1900, cxix, 668.

[2] The Journal, xxxv, 1010.

Children of aged fathers, he claims, are the saving leaven of the race, as regards longevity; the mother's reproductive period being limited as to time, she can cut no figure in the question, according to his views. In civilized communities, however, the tendency for the vigorous long-lived man to leave more children than the less robust is restricted—he has children generally by but one wife and she nearly his own age. Monogamy thus reduces him in this regard to the level of the inferior man and "robs the race of a number of individuals whose birth would diminish the racial tendency to disease in the later years and increase the racial span of life." This, he contends, increases the liability to certain diseases, especially those of advanced life, such as cancer, since the contribution to the species of the short-lived cancerous individual may be as great as that of his more physically favored brothers. The injurious influence of monogamy can not, however, be counteracted by discarding it, since that is a sociologic impossibility, as Dr. Campbell admits. He sees no remedy except in voluntary abstinence from marriage on the part of the unfit, and goes so far as to suggest that by judicious discrimination in this respect we may not only reduce the tendency to disease, but may even extend the span of life almost indefinitely.

There is no doubt that judicious regulation, not to say restriction, of marriage could improve the race, but there are some things in Dr. Campbell's theories that will hardly bear criticism. He apparently ignores the very great probability that the children of long-lived fathers begotten in their most vigorous maturity are likely to be better fitted to produce a healthy and long-lived posterity than those born in their decadence or old age. The only justification of his line of argument is that, by begetting children up to an advanced stage of life, they might furnish a larger quantity of descendants without regard to quality, which last is not supposed to have improved by the advanced age of the father or the great inequality of age in the parents. Polygamy is therefore not so certainly favorable to racial improvement as he appears to think; in fact, it might be distinctly unfavorable. According to his view, moreover, with the tendency to die at the close of the reproductive period, man ought to be much longer lived than woman, which is not the case. His paper is a suggestive one, but, like many others by some of the medical Weissmanites and Neo-Darwinians, it fails in a full appreciation of all the facts involved in the problem it treats.

MISMANAGEMENT IN THE BOER WAR.

Our English cousins are evidently passing through the same experiences that we had in regard to hospital management, or mismanagement, in the field. All kinds of charges and counter-charges are being made, some of which border on the sensational. The army medical department is receiving considerable censure, although most of it is directed against the government for its lack of appreciation of the necessities of the case and of the demands that would be made on the medical services by a large army fighting under such circumstances. When all has been said and cool judgment takes the place of hystericism, it will probably be found that no one is to blame, but that the trouble results from the fact that in time of peace there is little preparation made for war, as far as the medical department of the army is concerned. This experience may teach a lesson, and as a result the medical department in all countries will be more liberally treated in the future, but this is doubtful. The navy in all its departments is always ready for war. When the army is placed on a similar footing, then and not till then, will the basis for complaints of mismanagement cease to exist.

CONSUMPTION IN COLORADO.

The Colorado State Medical Society has appointed a committee or board consisting of the Secretary of the State Board of Health and the chief health officers of Denver, Colorado Springs and Pueblo, to investigate tuberculosis in that state. They are to make a thorough study of all the local problems of the disease and especially the question of its primary origination in the state, concerning which there appears to be much anxious difference of opinion. The report of their studies is to be given, as far as it can be made complete, at the next annual meeting of the society. There is reason to hope that the results of this investigation will have a very decided value and that they will relieve some of the apprehensions that now exist as to the dangers of the immigration of tuberculosis patients into Colorado. It is, of course, not to be expected that they will find that no cases of consumption originate in Colorado—it would be very remarkable if some did not—but the investigation, if thoroughly carried out, can not fail to deduce facts of interest and we trust will help to allay some of the excesive fear of contagion that may exist there as elsewhere in health resorts for consumptives.

ALCOHOLIC STIMULANTS NOT A NECESSITY.

Dr. Charles E. Woodruff, of the U. S. Army, in a communication in a lay journal, the *Detroit Tribune*, discusses the use of alcoholic stimulants, and claims that in certain states of exhaustion they are valuable. But he goes further than this and maintains that in some climatic and social conditions they are also essential. Thus he says, "As we go south, more of the normal people feel the need of stimulation to counteract the effects of the heat, until we reach lands where every one drinks moderately," and in another place [illegible] unnatural conditions of modern ci [illegible] and that "the liquor traffic [illegible] ly city life." His claim [illegible] is beneficial to soldiers in th futed from military statistics in a late (June 21) issue of the *Boston Medical and Surgical Journal* and hardly needs further notice, but a word at least can be given as to the other unguarded statement above quoted. The liquor traffic may perhaps be called an essential element in modern deadly city life, without which it would be far less deadly, but the doctor will be quoted far and wide as proclaiming it a sanitary necessity, especially by liquor dealers. His previous utterances as regards the need of liquor in the tropics have attracted considerable attention by the lay press. These later ones will probably attract more, and put him in a position before the public of advocating views which are more and more being actively repudiated by the medical profession, which he certainly can not desire.

THE TOXIN OF THE GONOCOCCUS.

In view of the prevalence of gonorrhea and of the obstinacy of this disease to treatment, all new facts in regard to the biology of its microbe must be of interest. De Christmas and others have demonstrated that the gonococcus elaborates toxic substances capable of producing suppuration and fever in animals, and a purulent urethritis in man. The latter is characterized by abundant pus formation and heals spontaneously in a few days. The toxic substance or substances are found partly in the bodies of the cocci, partly dissolved in the liquid of the culture medium. De Christmas states that animals may be immunized against the toxin by the inoculation of successively increasing doses thereof. These observations have been questioned by other writers who found the gonococcus more or less feeble in its power to produce toxin. Evidently the composition of the medium upon which it is grown plays an important rôle in the elaboration of toxin. Recently De Christmas, seeking some good method for making the effects of the toxin evident, studied the results of the intracerebral injections of gonotoxin. The resulting symptoms were so definite that he selected this method for studying various problems in the biology of the gonococcus—problems that present great difficulties of solution because of the well-known cultural peculiarities of this microbe. The injection of filtered cultures into the brain of guinea-pigs is followed by spastic and paralytic phenomena ending in great dyspnea and death about sixteen hours afterward. De Christmas reports a number of interesting observations based on more elaborate and diversified experiments of this nature. He finds that the toxin is present in solution in the culture medium (ascitic fluid 1 part, bouillon, with 1 per cent. peptone 2 parts); that it does not concern a diffusion of toxin from dead cocci, but an actual biologic function which is not exercised except under certain favorable conditions. The toxin is not dialyzable, and it resists heating to 60 C. for at least one hour, but it is changed by exposure to 75 C. for fifteen minutes. Subcutaneous injection of the toxin results in the formation of an antitoxic substance in the blood of the animals used. This antitoxin neutralizes the gonotoxin outside of the body, and when injected into the brain before the toxin is injected, or into the circulating blood, it suspends the toxic action of the toxin. If verified, these results may become the starting-point of further investigations that may bear fruit in the treatment of gonorrhea.

PHYSICIAN'S RIGHT TO REFUSE CALLS.

The lay press in Great Britain and in this country has been recently handling the old theme whether a physician has the right to refuse to answer calls. A London coroner's jury, it seems, denounced as inhuman the action of some doctors in refusing to attend a case, and the papers followed its lead. A prominent American journal admits the legal right of the physician to refuse his services, but says that more is expected from him than from the ordinary tradesman, and that we look for some spirit of self-sacrifice from the medical profession. The doctor, according to popular notions, must give his services wherever wanted and at all times, without regard to his own personal comfort or welfare, and his refusal is counted as inhumanity. This is a satisfying sort of self-righteousness, easily assumed, that disposes of other people's rights so freely. A physician has as good a right to refuse to answer a call for his services as has a mechanic, or a lawyer, and if he has good reasons, such as fatigue or overwork, no just charge of inhumanity can be made against him. He has also as good a right to refuse to work for nothing as any other man, and it would be better for the profession collectively if he oftener availed himself of this right. There is no profession that does as much for charity as the medical, and this is true to such an extent that a large section of the public has come to regard what is thus done for them as in the natural order of things and deserving of no acknowledgement. No one wishes to see any moral deterioration or increase of commercialism in the profession, and, indeed, there is no danger of its members as a class repudiating the honorable traditions from the past, but there is no need, on the other hand, that they should acquiesce in the unjust assumptions of pseudo-philanthropic posers, to lay down their rules of conduct and morals for them. That London jury was very probably made up of men who would, in their way of business, do far worse than the doctors whom, in their vicarious conscientiousness, they condemned, without scruple or remorse. As physicians we wish to exercise charity for all, even the offensively self-righteous, but the common cheap virtue of this kind in the daily press sometimes makes us tired.

DELAYED SUPPURATION DUE TO TYPHOID BACILLUS.

For a long time a discussion was waged as to whether or not the typhoid bacillus is a pyogenic organism; but the evidence would seem to have decided the question in the affirmative, the bacillus being found in pure culture in various suppurative processes. Sometimes such lesions have become manifest only many years after the primary infection. In one instance, the bacillus was found in a case of suppurative cholecystitis more than eighteen years after the original disease; in another, in a case of axillary abscess, seven years afterward; in a third, in a case of osteomyelitis, six years afterward; and in a fourth, in a case of abscess of the tibia, four years afterward. To these a further case is added by Bush and Symes[1] in which an abscess of the tibia persisted for seven years after an attack of typhoid fever. The patient was a woman, 25 years old, in whom, during convalescence from an attack of typhoid fever at the age of 18 years, a painful swelling appeared in the upper and anterior portion of the left tibia, which was incised, with the discharge of a quantity of pus. The wound was completely healed at the end of three weeks, but almost immediately a second collection of pus accumulated and it was discharged spontaneously. From time to time, there was a discharge from this wound, until within two years. When the patient came under observation, she presented a doubtful swelling over the front of the upper third of the left tibia at the site of an old scar, with much tenderness in the neighborhood. An incision was made over the scar, and pieces of bone were gouged away until the center of the bone was reached. A small bead of pus then appeared, and on the removal of more bone, an abscess-cavity containing a small sequestrum was disclosed. The cavity was scraped, and the sequestrum removed. Recovery was uninterrupted, and the severe pain that had been present for many years was relieved. On microscopic and cultural examination of the pus, the typhoid bacillus alone was isolated. In explanation of the manner in which the foci of suppuration are caused in cases of typhoid fever, it is suggested that the typhoid bacillus passes from the bowel into the portal system, is carried to the liver, and enters the biliary channels, and finally the gall-bladder, where it may excite suppurative cholecystitis, or form the starting-point of a biliary concretion. Sometimes, however, general blood-infection takes place, and local foci of suppuration are excited, either by the lodgment of bacteria in tissues of low vitality, or by masses plugging minute vessels.

---

[1] Practitioner, April, 1900, p. 413.

Medical News.

Dr. H. L. E. Johnson, Washington, D. C., is arranging for reduced rates of transportation to the meeting of the Third Pan-American Medical Congress at Havana, Cuba, Dec. 26-29, 1900.

Dr. William Osler, Baltimore, delivered the address at a conversazione of the Medical Graduates' College and Polyclinic, London, on July 4. His subject was "The Teaching of Practical Medicine."

About the middle of August the Columbia River quarantine station will be ready for service. Work on the wharf and buildings for the disinfecting machinery and bath-rooms was commenced this week and under the terms of the contract must be finished within sixty days.

At the coming meeting of the Canadian Medical Association to be held at Ottawa, Sept. 12-14, Mr. Edmund Owen, London, England, will deliver the address in Surgery. Others who will take part are: Drs. Shattuck, Boston; Louis Gerster, A. M. Hamilton and Dr. Fox, New York City; Nicholas Senn, Chicago. Dr. William Gardiner, Montreal, will deliver the address in gynecology.

Maternity Hospital.—An effort is being made to establish a maternity hospital at San Juan. The city government has given the land, and the Woman's Aid Society of Porto Rico is trying to raise $25,000 for the erection and equipment of the buildings. This Society is made up mostly of wives of army officers and has done much-neded work in caring for great numbers of suffering women and children.

Ambulance Work in South Africa.—Dr. J. R. MacNamara, of Chicago, who has been in South Africa in charge of the "Chicago Ambulance Corps," has returned home, after the practical dispersal of the corps. He said that he could not fulfill any of the functions of an ambulance director without having an adequate staff to assist him, and that under the conditions that existed in the Boer army, the operation of ambulance organizations, as we understand them, was an impossibility.

The "Three D's" Crusade.—At the meeting of the Oxford branch of the National Association for the Prevention of Consumption, Prof. Clifford Allbutt sketched clearly the main facts as to the nature of the disease and indicated the principles on which preventive measures must be based (*Brit. Med. Jour.*, June 23). He epitomized the precautions as an active crusade against the three D's—dump, darkness and dirt—a crusade which, as he said, every individual could carry out in his own home. In getting rid of these evils, they would at the same time be getting rid of many other pests besides tuberculosis, and would be raising the standard of the general health. There is wisdom in inculcating the general principles of hygiene in public meetings, for general hygiene appeals most strongly to the public mind when its application to a special evil is forcibly impressed.

OHIO.

Cincinnati.

Dr. E. W. Mitchell sails for Europe, July 7, and will be away three months.

The Cincinnati Academy of Medicine devoted the evening of June 25 to the memory of the late James T. Whittaker, a notice of whose death appeared in The Journal, June 9.

At the recent examinations for entrance into the United States Marine-Hospital Service, Drs. Edward Francis and John Boggess were two of the six successful candidates, out of forty who competed.

APPOINTMENTS IN COLLEGE OF MEDICINE AND SURGERY.

The changes announced in the faculty for the coming year are: Dr. David De Beck, professor of ophthalmology; Dr. H, P. Dickmen, assistant; Dr. Clark Hiller, physiology; Dr. H. Freudenberger, pathology and bacteriology; Dr C. T. Pearce, dermatology and genito-urinary diseases.

WISCONSIN.

Dr. W. R. Hicks has been appointed assistant-surgeon in the United States Marine-Hospital Service, and will be stationed at Menomonie.

The Board of Medical Examiners has granted licenses to over one hundred physicians, who had already registered, but who wished this further qualification in order to become members of the State League of Licentiate Physicians, which has recently been formed.

DELAWARE.

At the annual meeting of the Medical Examining Board, Dr. Irving Vallandingham was elected president, and Dr. J. H. Wilson, secretary.

At the recent examinations conducted by the Medical Council of Delaware, nine physicians were licensed to practice within the state.

KENTUCKY.

Dr. E. B. McCormick, of Owensboro, has been appointed superintendent of the Western Lunatic Asylum at Hopkinsville.

KENTUCKY SCHOOL OF MEDICINE.

The fortieth commencement exercises of the Kentucky

School of Medicine were held on the evening of June 26. This school now requires a four years' course before granting a diploma, and is in a flourishing condition. The doctorate address was delivered by Dr. Roswell Park, Buffalo, N. Y. Degrees were conferred on thirty-six graduates.

TUBERCULOSIS.

The Governor of Missouri has issued an edict quarantining cattle from Kentucky because of the alleged existence of tuberculosis among them. Tuberculosis exists among cattle in almost every part of the state and it needs such quarantines to arouse the legislature to the necessity of waging war against this disease. The State Board of Health petitioned the legislature to make an appropriation to prosecute this work, but was unsuccessful. A large sum of money is awarded the boards of health in other states to use in this manner, but Kentucky has only $5000 appropriated for all its work, the inspection of cattle included.

OSTEOPATHY.

All states have been looking to Kentucky as to its course in the osteopathy cases, especially since the masterly decision of Judge Sterling B. Toney, of Louisville, declaring that osteopaths could be prosecuted under the present laws, that they were practicing medicine and should hold regular diplomas from a regular or other recognized school. The case in which this decision was rendered was carried to the Court of Appeals and a decision just rendered reverses the action of the lower court and grants a perpetual injunction against the State Board of Health from interfering with the osteopaths! The opinion holds that the American School of Osteopathy and similar schools are not medical colleges within the meaning of the law, and the act of the legislature does not apply to the graduates from these schools; a graduate from one of these schools is in no sense a physician or surgeon and does not practice medicine. It holds that they may be prosecuted for prescribing or administering medicine or performing surgical operations without holding the certificate of the State Board of Health as prescribed by law.

NEW YORK.

The Associated Physicians of Long Island met in Northport, June 18. A business session was held in the morning and the afternoon was spent yachting on the bay.

Dr. Arthur Ross has been appointed professor of diseases of the throat and nose at the Albany Medical College, to fill the vacancy caused by the resignation of Dr. John M. Bigelow, who has been made emeritus professor.

New York City.

Dr. Smith Ely Jelliffe left June 28 for a trip through Norway and Sweden.

Rear-Admiral James Rufus Tryon, U.S.N. (Retired), has been appointed physician-in-chief of Sailors' Snug Harbor, Staten Island.

Dr. Reginald H. Sayre sailed for Europe June 30, on the *Lucania*.

SENEY HOSPITAL.

The new pavilion for surgical operations, that is attached to the Methodist Episcopal Society, has been opened to the public. It is large, well lighted and well equipped with all modern appliances, and is fire proof. At the dedicatory exercises, Drs. Geo. R. Fowler, John B. Roberts and Lewis S. Pilcher made addresses.

MARYLAND.

Plans for the new building of the Peninsular General Hospital, at Salisbury, have been prepared. It will be a four-story brick building with two three-story octagonal wings, and will have sixty-six beds.

MEDICO-PHARMACEUTICAL ETHICS.

At the recent meeting of the Maryland Pharmaceutical Association, held at Hagerstown, seven rules were submitted which had been drafted by a joint committee of three each from the Association and from the Medical and Chirurgical Faculty of Maryland. Six were adopted: That pharmacists shall refuse to prescribe for customers except in emergency cases, and physicians shall carry emergency remedies only; substitution of one article for another in prescriptions is prohibited; physicians shall regulate their charges and pharmacists theirs; pharmacists not to refill prescriptions when directed by doctors not to do so; druggists must see doctors before filling prescriptions supposed to contain errors; druggists not to disclose contents of prescriptions to customers. These rules will be submitted to the Medical and Chirurgical Faculty for action. The Association refused to endorse the rule that druggists shall not place caution labels unless ordered by the doctor.

Baltimore.

Dr. Wm A. Fisher sailed for Europe, June 16.

Dr. J. J. Carroll will spend the summer in Europe.

Dr. Wm. Osler is in England, where he will remain for the summer.

The College of Physicians and Surgeons has appointed Drs. J. Hall Pleasant and Thomas R. Brown, both graduates of the Johns Hopkins Medical School, as professors in clinical medicine.

The remains of the late Stephen S. White, passed assistant-surgeon U. S. N., who died recently at Sitka, Alaska, arrived in Annapolis, June 27, and were interred at the Naval Academy Cemetery.

Dr. John C. Hemmeter sailed for Europe June 27. He will deliver addresses before the British Medical Association at Ipswich, and before the International Medical Congress in Paris.

The Barnard Sanitarium was incorporated June 27, by Dr. James L. Barnard and others. The purpose is to establish a medical and chirurgical hospital and a nurses' training school. The capital stock is $500, divided into 500 shares of $1 each.

A children's ward has been opened at the City Hospital, and has been furnished by a lady in memory of her son. A separate apartment is provided for each child, and the apartments communicate by folding doors with an intervening play-room. There are already ten inmates.

DEATH DURING CHLOROFORM ANESTHESIA.

On June 20, a man aged 52 died at the University Hospital, during chloroform anesthesia, preliminary to an operation. Three months previously, he had fallen and broken his leg. Under treatment the bones united, but when he began to use crutches, he suffered from severe shooting pains in the limbs. He was advised to have the bones rebroken and reset, and it was while he was being chloroformed, preparatory to examination, that fatal narcosis suddenly took place. The anesthesia was being conducted with an Esmarch inhaler, by one of the resident physicians of the hospital, and all approved measures were employed in the efforts at resuscitation.

CONVICTED OF MANSLAUGHTER.

Dr. George C. Worthington was sentenced to ten years in the penitentiary, for manslaughter, June 27. This is the maximum penalty provided by the law. He was twice convicted of causing the death of Miss Amelia Miller on June 30, 1899, by a criminal operation. After the first conviction, a new trial was granted because one of the jurors was under age. Motion for a new trial was overruled June 26, by the supreme bench. It is said that his attorneys will take the case to the Court of Appeals; meanwhile the judge has refused him bail.

JOHNS HOPKINS HOSPITAL REPORT.

The report of the Johns Hopkins Hospital for the year ending January 31 states that there were in the hospital on that date, 264 patients, of whom 133 were males and 131 females. Of these 203 were white and 61 colored. During the year 3816 patients were admitted, 1963 males and 1853 females. The total number treated—including those remaining from the previous year—was 4074, viz.: white, 3273; colored, 801. Of these 3002 were discharged well or improved, 143 were unimproved, 90 transferred to other departments, and 254 died, while 321 applicants were not treated. The mortality was 6.23 per cent. of the cases treated. The daily average under treatment was 263. The total number of visits made by patients to the dispensary was 58,870.

ILLINOIS.

At the meeting of the Jacksonville Medical Club, held June 16, H. C. Campbell was elected president; Edward Bowe, vice-president; D. W. Reid, secretary, and E. F. Baker, treasurer.

Chicago.

Dr. J. T. Stanton sailed for Europe, June 30.

Dr. W. M. Harsha sailed for Glasgow on the *City of Rome*, June 30.

Dr. Palmer Findley, medical inspector, has returned to duty after a year spent in the hospitals of Europe.

Dr. M. Meyerovitz has been reappointed by Governor Tanner, a member of the State Board of Health.

At the commencement exercises of the German Hospital Training School for Nurses, held June 26, Dr. Julius H. Hoelscher delivered the address.

By the will of the late T. B. Blackstone, $25,000 has been left to Passavant Memorial Hospital; $25,000 to St. Luke's Hospital, and $25,000 to the Chicago Relief and Aid Society.

The commencement exercises of the Harvey Medical College were held June 22. Degrees were conferred on a class of seventeen by the president, Dr. Frances Dickinson.

Dr. E. S. Pettyjohn has sailed for Europe. He will make extensive examinations of different hospitals for the insane in Germany.

At a meeting of the Chicago Society of Internal Medicine, held June 28, the following officers were elected: president, Dr. John A Robison; vice-president, Dr. James B. Herrick; secretary, Dr. Edward F. Wells; treasurer, Dr. M. L. Goodkind. Censor for the North Side, Dr. Henry B. Favill.

The Fourth of July in Chicago was attended by less than the usual number of casualties. One man was killed by a stray bullet, and forty-four were injured by fire-works during the day. Heat caused seven deaths and ten prostrations. Seventeen were injured during the Pullman road race.

HEALTH DEPARTMENT.

There are now twelve smallpox patients in the Isolation Hospital. All with one exception are doing well, and this one will probably recover. None of the patients has ever been vaccinated. Dr. Spalding, chief medical inspector, states that of the fifty-nine smallpox patients who have come under the notice of the department in the last sixteen months, not one had a mark denoting successsful vaccination. Four smallpox patients were taken from one house on June 16 and 17, members of one family, none of whom had been vaccinated. Four other members of the same family and a number of neighbors who had been vaccinated, were exposed again and again, before the nature of the disease was appreciated, and none contracted the disease. The last patient taken to the Isolation Hospital was a waiter in a club, a member of which was taken ill with a pustular eruption not diagnosed as smallpox, and eventually returned to his home in the country. On June 28, just fourteen days after this waiter had been exposed, he was seized with smallpox, and is now seriously ill at the hospital. Other vaccinated employees of the same club, who had been exposed in the same way, have not contracted the disease.

PENNSYLVANIA.

Through the will of Mrs. Mary Yost, a resident of Pottstown, the sum of $500 has been given the Pottstown Hospital and a like sum to the Presbyterian Hospital at Perth Amboy, N. J.

OLEOMARGARIN LAWS.

It is said that the Dairy and Food Commissioner recently returned to Harrisburg from Philadelphia, where he had been looking after matters relative to the violations of the oleomargarin law. It is understood that he informed the agents that if they did not obey the instructions of his office they would be discharged. Since the wholesale arrest of parties violating the oleomargarin laws of the state, a considerable number of disclosures have been made public, relative to the manner of ferreting out this crime. At a recent meeting of Pomona Grange No. 5, of Columbia and lower Luzerne counties, a resolution was adopted to the effect that there had been sold 12,000,000 pounds of oleomargarin in Pennsylvania, and further that "whereas the proven complicity of the State officials with violators of the laws passed to prevent injury and fraud, financial and physical, to the people merits the sincerest censure," etc. The resolution ends by demanding the resignation of the Secretary of Agriculture and other officials. It is claimed that the sale of this amount of oleomargarin means a loss of $4,000,000 to the dairymen of the state.

Philadelphia.

Through the will of Charles G. Trucks a contingent bequest of $2000 will revert to the Pennsylvania Hospital for the Insane.

The following resident physicians have been chosen to compose the resident staff of the German Hospital: Drs. J. W. Curry, Frank Dye, Paul G. Mueller, Fred M. Paul, and G. H. Hunsicker.

The amount of suffering from the heat during the last week of June was terrible. The extreme heat began on June 29, and continued three days. On the 27th there were 3 prostrations reported; on the 28th, 14, and on the 29th, 5.

On June 29, 11 cases were called before Magistrate Stratton for alleged violations of the pure food laws. Most of the defendants were charged with selling oleomargarin for pure butter, and were held in bail, ranging from $400 to $800.

Foundations are being laid for the annex to St. Timothy's Hospital to be known as the Percival Roberts Memorial. The new structure will be three stories in height, and 49 by 139 feet. It will be constructed of brick and terra cotta, and when finished will have cost $55,500.

On account of the noise and tumult generally aroused on July 4, the mayor gave orders to prevent the firing of guns, pistols, or explosives of any kind within a square of the hospitals; and further, that if anyone was ill at a private house and a request was made to abate the noise, the officer must see to it without further orders.

DIPHTHERIA.

Three cases of diphtheria were discovered in the Italian quarter of West Manayunk, June 23, and an epidemic is feared. It is said that all the residents in the neighborhood are in the habit of slaking their thirst by placing their mouths to a pipe which leads to an adjoining spring. So far no cases have occurred among adults. Prompt action has been taken by the officials to prevent the further spread of the contagion.

CONTAGION IN WALL PAPER.

The work of scientists along the lines of preventive medicine is gradually being disseminated among the laity. The latest indication is the fact that the "Paper Hangers' Union" has issued a public address warning the people against the danger of repapering houses over old paper, on account of contagion. One case is mentioned in which a member refused to place new paper over the old, in a room in which there had been a death from smallpox. There are about 800 paper hangers in the city, 500 of whom belong to the Union.

CANADA.

The following have been appointed house physicians at the Winnipeg General Hospital: Drs. R. J. Brandson, John Halpenny, Jas. Little, and A. R. Taylor.

Quarantine Officer Dr. J. C. Sinclair, at Rossland, B. C., is at present having considerable trouble with the people coming in over trails, and thus evading quarantine regulations and proper inspection.

Dr. Cameron, who has been in charge of the smallpox cases in the quarantine station at Winnipeg, has been relieved from his duties, as the patients have all fully recovered.

EXTENT OF LEPROSY IN CANADA.

In answer to questions in the Dominion Parliament by the Hon. Colonel Prior, member from British Columbia, the Minister of Agriculture stated that there were nineteen lepers in the lazaretto at Tracadie, fourteen being from the Province of New Brunswick, one from Prince Edward Island, three from Manitoba (the disease having been contracted in Iceland), and one from Nova Scotia. One of the Manitoba cases

B. B. Davis, W. L. Dayton, R. C. Moore, F. S. Owen, J. L. Sutherland.—Total, 7.

Report on the Pathological Exhibit.

When it is remembered that the movement to inaugurate a Pathological Exhibit at the Atlantic City meeting of the ASSOCIATION was not begun until the fall of 1899, the results achieved are little short of remarkable. The large amount of labor necessary in placing the Exhibit and the inability of the Committee to learn beforehand what it would contain, have made the preparation of a catalogue out of the question. For similar reasons classification was in many respects faulty. Only a summary of the exhibits is possible in the report, which follows:

Section A—Bacteriology and Clinical Diagnosis.		
Cultures of various pathogenic bacteria	80	
Common urinary deposits	15	
Stained preparations of various blood conditions	30	125
Section B.—Public Hygiene.		
Traveling bacteriological laboratory for diagnostic purposes	1	
Cultures of bacillus icteroides	16	
Cultures of plague bacillus	16	
Diseased meats	97	130
Section C.—Retrogressive and Progressive Tissue Changes. Tumors.		
Gross specimens	14	
Photographs	8	22
Section D.—Disturbance of Development.		
Gross specimens	3	
Photographs	3	6
Section E.—Diseases of Blood-making Organs and Ductless Glands.		
Gross specimens	12	12
Section F.—Diseases of Circulatory System		
Gross specimens	29	29
Section G.—Diseases of Respiratory System.		
Gross specimens	15	15
Section H.—Diseases of Gastro-Intestinal Tract.		
Gross specimens	83	83
Section I.—Diseases of Urinary Organs.		
Gross specimens	91	91
Section J.—Diseases of Reproductive Organs.		
Gross specimens	25	
Photographs	10	35
Section K.—Diseases of Nervous System.		
Gross specimens	25	
Sections of entire brain	9	
Pathological brains, hardened and infiltrated with wax	12	
Photographs of pathological brains	50	
Drawings	25	121
Section L.—Diseases of Bones and Joints.		
Gross specimens	17	17
Section M.—Diseases of Eye.		
Gross specimens	91	
Photographs	18	109
Section N.—Dermatology.		
Gross specimens	2	
Photographs illustrating histopathology of skin	27	
Photographs of cases	44	
Photomicrographs of skin yeast	25	
Cultures of skin yeast	18	116
Secti		
types of insane	500	
f criminals	42	
Skiagrams	43	
Miscellaneous photographs	82	667
Section P.—Miscellaneous exhibits	32	32
Grand Total		1610

Colorado State Medical Society: A. M. Holmes.—Especially worthy of note in this collection were a rhabdo-myosarcoma, an intradural tumor of the spinal canal and a teratoma.

Indiana State Medical Society: Frank B. Wynn.—The largest quota of gross specimens came from this society, which has had a pathologic exhibit at its annual sessions for three years past

Kentucky State Medical Society: James M. Bullitt.—Rare specimens in this display were one of actinomycosis of the lungs and a mammoth ovarian cyst weighing 245 pounds. The effect of the collection was enhanced by the use of Kaiserling fluid as a preservative.

Missouri State Medical Association: Hugo Summa.—This was a collection of high average excellence. Among the rare specimens were pancreas annulare and pentastoma constrictum.

New Jersey State Medical Society: F. W. Bailey and John Bruyere.—The most interest specimens in this display were of cerebral porencephalia, horse-shoe kidney and invaginated intestine.

New York State Medical Association and Carnegie Laboratory: Edward K. Dunham, Leon T. Lewald, Roland E. Benville, D. Hunter McAlpin. Jr., and J. W. Draper Maury.—The collection from New York was conspicuous for the average excellence of the specimens and the beautiful manner in which they had been prepared, Kaiserling fluid having been used to preserve the natural colors. Beautiful illustrations were thus given of the different stages in pneumonia, of pulmonary hemorrhage and tuberculosis, acute and chronic. A remarkable specimen of congenital cystic kidney was in the exhibit.

Wisconsin State Medical Society: H. V. Würdemann and Gustav A. Kletzsch.—This exhibit consisted of a fine collection of diseased eyes mounted in gelatin.

Pepper Laboratory of Clinical Medicine, Philadelphia: Alfred Stengel, C. Y. White. Samuel S. Kneass, George M. Purves, and Joseph Walsh.—Demonstrations were made of the Widal test for typhoid fever. Cultures and cover-slip preparations of the pathenogenic bacteria were also shown; also stained preparations of the various blood conditions, as malaria, leukemia, pernicious anemia, etc., all of which were made interesting and instructive.

Polyclinic Laboratories, Philadelphia: T. S. Kirkbride, Jr., H. D. Williams, Edward A. Shumway and J. Colton Deall—In this exhibit were numerous macroscopic mounts of diseased eyes, with accompanying microscopic sections. One of metastatic carcinoma of the choroid was particularly interesting. It also included photographs of ruptured tubal pregnancy and some ingenious laboratory devices of original pattern.

Medico-Chirurgical College, Philadelphia: Mihran K. Kassabian.—In this exhibit a large number of skiagrams were presented showing foreign bodies, fractures, vesical calculi, and tuberculous conditions of the lungs.

Johns Hopkins Hospital, Baltimore, Md.: William H. Welch and Harry T. Marshall.—In this collection the sequence of pathological changes found in typhoid fever and tuberculosis of the intestines was beautifully illustrated

Lakeside Hospital, Cleveland, Ohio: W. T. Howard, Jr., and Roger G. Perkins.—This collection was excellent. Among the rarer specimens were a myoma of the uterus complicating pregnancy of only a few weeks' duration, typhoid ulcer of the larynx and congenital pia-arachnoid cyst of the cerebellum.

New York Pathological Institute, New York City: Ira Von-Gieson and Henderson B. Deady.—Many original drawings were exhibited, a number of gross slides of the brain and a unique and complete method of keeping records of cases, autopsies, etc.

Government Hospital for Insane, Washington, D. C.: A. B. Richardson and I. W. Blackburn.—This exhibit was highly creditable to the pathologic work done in the institution. The large collection of photographs, illustrating the different types of insanity was especially interesting. Noteworthy among the gross specimens were those of brain tumor, hydrocephalus, and extreme atrophy of the convolutions.

U. S. Marine-Hospital Service: M. J. Rosenau.—A very complete traveling bacteriological laboratory, for diagnostic purposes was displayed; also cultures of the bacillus icteroides and the plague bacillus.

U. S. Bureau of Animal Industry: D. E. Salmon.—Diseased meats were collected from various government inspecting stations, and preserved in cold storage, thus enabling visitors to see them in a comparatively fresh state. This display was la and made an impressive object-lesson in public hygiene. The extensive and multifarious lesions of tuberculosis in animals constituted the striking feature of the exhibit.

Besides the foregoing exhibitors there were many individuals who sent single specimens. It is impossible in this brief report to give all their names. In this list would be included President W. W. Keen, who contributed rare specimens of aneurysm of the aorta and of the renal artery.

The successful inauguration of the first pathological exhibit of the Association has been alike gratifying to the executive officers and to the committee which had the work in charge. It was a wholesome change to have a large exhibit free from commercialism. The Association expressed its approval by making the feature permanent and making a liberal appropriation for its continuance. The valuable service rendered by the large corps of pathological workers can not easily be repaid. No stronger evidence could be adduced of the high scientific spirit and unselfish devotion to the advancement of medical science, which animated their efforts. Their sole compensation is in the consciousness of a great duty well performed and the heartfelt approbation of professional colleagues.

In testimony of appreciation as to the practical and scientific value of the exhibit, the following expressions are quoted from a large number similar in character, recorded in the Register. Roswell Park: "A most interesting and valuable feature of the meeting." Ferd C. Valentine: "Unqualifiedly the most important and instructive contribution to the advance of medical science in the Association. The authors of this exhibit are doing more than if they contributed a thousand papers." Wm. E. Quine: "The most instructive feature of the meeting and extremely creditable to all who contributed."

Prof. Wm. H. Welch, in a letter to the committee, says:

> You have done a really great work for the Association, and immensely increased the interest and importance of our meetings by the exhibit and the formation of a Section on Pathology.

Virchow, the renowned father of modern pathology, writes thus concerning the movement:

> I have received your letter of April 14, concerning the pathological exhibit. As I wish to help you in this important work, I will send you from Berlin upon my return there, some printed papers. I hope that your countrymen will recognize the intimate relationship of a practical knowledge of pathology, not only to expert diagnosis, but also to successful treatment.

Deaths and Obituaries.

S. S. Fowler, M.D., died in Marionville, Pa., June 19. He was born in Manchester, England, but spent his youth in Canada, where he was educated in the Toronto schools. He was graduated from the Medical Department of the University of Michigan; and after two years' service in the Civil War, located in Chicora, Pa., where he lived until 1878, when he moved to Marienville. He was vice-president of the Pennsylvania State Medical Association; and had twice represented his county in the legislature.

Alfred Hitchcock, M.D., Farmington, Maine, died June 14, aged 41 years. He was graduated from Bowdoin College and from the Portland Medical School. He then served as house physician in the Maine General Hospital and practiced in Strong, before locating in Farmington. He was a member of the Franklin County Medical Association, and of the Maine Medical Association.

Joseph D. Smith, M.D., St. Joseph, Mo., died June 21, aged 72 years. He was born in Virginia, and educated in Louisville, Ky. During the Civil War he was surgeon of the Ninth cavalry, Missouri State Militia. After the war he located in St. Joseph, where he was for a time professor in Ensworth Medical College.

J. M. McNulty, M.D., city health officer, died in Santa Barbara, Cal., June 23, aged 74 years. He was graduated from the Geneva (N. Y.) Medical College in 1846. For a number of years he practiced medicine in San Francisco, but, owing to the necessity for a change of climate, located in Santa Barbara fourteen years ago.

Lloyd N. Horwitz, M.D., died in Helena, Mont., June 23, aged 38 years. He was graduated from the Jefferson Medical college in 1882, and afterward served for some time as resident physician in the Philadelphia Hospital.

T. Sumter Means, M.D., Spartanburg, S. C., died June 18, aged 68 years. He was graduated from the medical department of the University of Pennsylvania in 1859. He began the practice of his profession in Glenn Springs, but twenty years ago moved to Spartanburg.

William F. Howard, M.D., Lawrence, Mass., died at his home, June 14, of typhoid fever, aged 31 years. He was graduated from the Bellevue Hospital Medical College in 1896. He was a member of the staff of the Lawrence General Hospital.

Samuel Luchsenger, M.D., Milwaukee, Wis., died June 23, following an operation for appendicitis. He was graduated from the Milwaukee Medical College in 1898.

George S. Ward, M.D., Newark, N. J., died June 25, aged 73 years. He was graduated from the College of Physicians and Surgeons in New York City in 1849.

King Wylly, M.D., University of Virginia, 1869, of Savannah, Ga., formerly of Sanford, Fla., died suddenly from apoplexy at Saratoga, N. Y., June 24, aged 50 years.

Henry Leinfelder, M.D., Prairie du Chien, Wis., died June 20, after an operation for appendicitis. He was a graduate of the Milwaukee Medical College of the class of '97.

F. M. Logsdon, M.D., Bieville, Texas, died June 16, aged 45 years. He was graduated from the Louisville (Ky.) Medical School in 1892.

J. W. Wingard, M. D., Martinsburg, Pa., died June 14, aged 64 years. He was graduated from the University of Pennsylvania with the class of 1860.

B. W. MacNichol, M.D., Jefferson Medical College, 1884, died in Westchester, N. Y., June 22.

DEATHS ABROAD.

We note the deaths of:

Professor Korsakoff, of Moscow, the author of numerous works on neurology, etc., editor of the journal established by the Pirogoff Medical Society, and co-editor of the *Klinitchesky Journal*.

Prof. C. T. Crudeli, of Italy, senator and formerly member of the medical faculty at Rome.

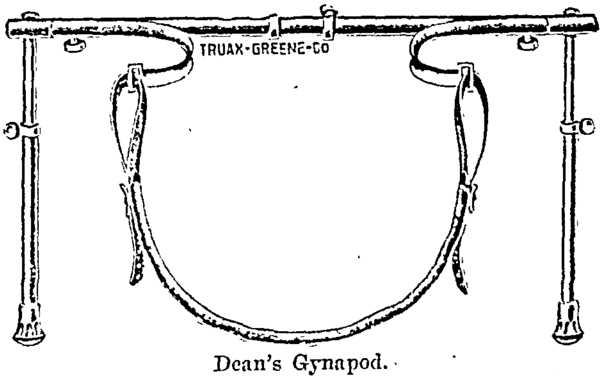
New Instrument.

New Leg Holder Securing a Perfect Lithotomy Posture Without Assistants.

BY WILLIS W. DEAN, M.D.

SIOUX CITY, IOWA.

The crutch here represented is made of light gauge bicycle tubing of various sizes, which telescope one within the other both when adjusted and when packed for transportation. It consists essentially of a cross-bar made in three separate pieces, each twelve inches long, the two outer and larger pieces telescoping the center one, working on it with a sliding motion, and capable of being fixed at any required length by set-screws. It also has two bands or half circles, also adjusted by set-screws, that slide on the cross-bar, and fix the thighs at any required angle from the body. Into each end



Dean's Gynapod.

of the bands are eyelets to which is attached the strap that passes over the shoulders. When in working order, the cross-bar will be under the knees, and the bands around the inner portion of the thigh immediately above the knees. This will give any position desired, and to maintain that position I have devised leg attachments, also made of tubing, and sliding on each end of the cross-bar. The legs are each made in two parts, and may be lengthened and shortened with ease. On the distal end of each is placed a crutch-cap to prevent slipping when adjusted for work. This is a very satisfactory device, as it secures the lithotomy posture, and fixes the legs at any desired angle from the body. It can be adjusted and used on any table, chair, bed or lounge, is aseptic throughout, and weighs in its entirety less than three pounds. It is inexpensive, very portable, and the cross-bar and legs can be packed in two pieces, the greatest length being one foot.

Miscellany.

Program of Entertainments, International Medical Congress.—Aug. 2, the day on which the Congress opens, a fête will be given in the evening by the president of the council in behalf of the French Government.

Aug. 3 —A fête will be given in the evening by the President of the Congress.

Aug. 5.—Reception for the members of the Congress, by the President of the Republic, at the Palais de l'Elysée.

Aug. 7.—A fête will be given by the Municipal Council of Paris in the Salons of the Hôtel de Ville.

Aug. 8.—A fête will be given in the evening in the Palais du Sénat and the Jardin du Luxembourg, by the officers and organization committees of the Congress.

Other entertainments have been arranged in most of the Sections. The wives, daughters and sisters of members are included in the invitations to these entertainments. A committee of ladies has been formed to receive and entertain the wives, daughters and sisters of members of the Congress.

Pentosuria.—Among the group of glucoses are found bodies containing five carbon atoms and carbon and oxygen in the proportion to form water. These bodies are called pentoses. Salkowski and Jastrowitz (*Centralblatt f. die Med. Wissenschaften*, 1892) have found pentose in diabetic urine. Kütz and Vogel (*Zeitschrift f. Biologie*, 1896) have found pentose in the urine of diabetes mellitus and diabetes induced by phloridizin respectively. Since the quantity of pentose excreted was insignificant, and has been found in connection with glycosuria, its detection was of no practical value. Later, however, Blumenthal (*Berliner Klin. Woch.*, 1895, No., 26, 1897, No. 12) and Salkowski (*Zietschrift f. Physiologische Chemie*, 1899) have reported each one case and recently Biat (*Zeitschrift f. Klinische Medizin*, 1900, p. 473) reported two additional cases of chronic pentosuria wherein this carbohydrate was excreted by itself. Since urine containing pentose gives the same reaction as grape-sugar with Trommer's test and Fehling's solution, and such a patient may be subjected unnecessarily to the hardships of the restricted diet of a diabetic, it is obvious that in order to avoid such blunders, all urine containing sugar when detected by the above tests should be controlled by other tests.

Pentose, unlike grape-sugar, is unfermentable, and does not polarize light to the right. The general use of the polarimeter is precluded on account of its cost, but the fermentation test should be made with Einhorn's cheap fermentation apparatus, which requires but a few minutes to prepare. Notwithstanding the fact that only four cases of chronic pentosuria have been reported up to the present, it is to be expected that when the differential tests are made in all urine containing sugar, the number of cases of pentosuria will increase, and eventually some light will be thrown upon the origin and significance of this hitherto unexplained phenomenon.

Can This be True?—The Illinois State Board of Health has just learned that a medical college, a member of the Association of American Medical Colleges, and one which was in good standing with this Board, admitted to the senior class of the institution last January, and is about to graduate, an applicant who presented evidence of having taken one course of lectures in a medical institution in Chicago, and of having "passed the first and second doctorate" in "the University Libre of Brussels" in November, 1899.

According to the records of the State Board of Health the medical history of this candidate is quite interesting. It appears that he practiced illegally in Chicago in 1894, and to avoid prosecution appeared before this Board to undergo examination in the undergraduate branches. He then claimed to have studied medicine for four years and had attended three courses of lectures in the Amsterdamche Universeit, Holland. Failing in this examinataion he became connected with the so-called "Illinois Health University," and with J. Armstrong, T. A. Bland and other lesser lights, issued diplomas to all comers until the supreme court of the state, in 1897, deprived this concern of its corporate privileges. Later, with the persons named he conducted the so-called "Independent Medical College," the immediate successor of the "Health University," and disposed of diplomas as heretofore. According to the published announcements, he held the "chair" of Practice of Medicine in both institutions.

Being convicted of illegally practicing medicine in 1898, on suit brought by the State Board of Health, this applicant who passed the "first and second doctorate," went to Michigan, and shortly aftetrward, as agent of the "Independent Medical College" took a trip to India, in which country he disposed of many hundred "diplomas" issued by this corporation. He returned to the United States late in 1899, and it is presumed by the Board, that on his route he dropped off at Brussels and, visiting the "University Libre," passed the "first and second doctorates."

The secretary of the Illinois Board, in commenting on the matter, to the dean of the college in question, makes the following pertinent remarks:

"For the information of this Board I will ask if it is the custom of your faculty to grant two years' advanced standing to persons who present credentials showing that they have passed examinations at certain universities in the United States and abroad? I can see no evidence of attendance upon any courses of lectures; in fact, I do not believe that you hold there was any such. Were the examinations referred to, the passing of the "first doctorate" and the "second doctorate," bona fide, and taken in any reputable university in the world, there would be no justification whatever for the granting of advanced standing. Your action is not only in violation of the rules of this Board, of the Association of American Medical Colleges, but also of your own published requirements, which state in effect that you demand of each student as a condition of graduation an attendance upon four full courses of lectures in four separate years."

Sanatorium for Lepers in France.—It is estimated that there are about four hundred lepers in France. They are scattered about in Brittany, in the Pyrenees, on the shores of the Mediterranean, and in Paris, where they number 150. Among the lepers there are missionaries and nurses who have fallen victims to their devoted care of sufferers in other countries, and officials and soldiers who have contracted the disease in the colonies. An anti-leprosy committee has recently been formed on the initiative of Dom Santon, a member of the Benedictine Community of Ligugé, who is also a doctor of medicine, for the care of the lepers in France and the prevention of the spread of the disease. Dom Santon has for many years past devoted himself to the study of leprosy, traveling for that purpose in many parts of the world. After conference with the Council of Hygiene he has acquired a property in the Vosges, where he proposes to establish an asylum for lepers to be called the St. Martin Sanatorium. The plans have been approved by the French Government.—*Brit. Med. Journal.*

"Osteopathic" Examining Boards.—The osteopaths of Ohio wanted a State examining board of their own. All other empirics or quacks would doubtless also like to be examined by boards of their own choosing. This would make all examining boards superfluous.—*N. Y. Med. Journal.*

Societies.

COMING MEETING.

Michigan State Medical Society.—Mackinac Island, July 11-12, 1900.

Columbia County Medical Society.—The annual meeting of this Socity was held in Bloomsburg, Pa. June 10. The officers elected were: president, J. S. John, Bloomsburg, first vice-president, A. B. McRae, Berwick; second vice-president, H. W. McReynolds, Bloomsburg; secretary and treasurer, W. M. Reber, Bloomsburg.

Sioux Valley Medical Association.—The fifth annual meeting of this Association was held in Sioux Falls, S. D., June 20-22. The following officers were elected: president, J. N. Warren, Sioux City, Iowa; first vice-president, M. W. Richey, Le Mars, Iowa; second vice-president, G W. Cross, Yankton, S. D., secretary, G. G. Cottam, Rock Rapids, Iowa; treasurer, S. A. Brown, Sioux Falls, S. D. The 1901 meeting will be held in Sheldon, Iowa.

Central Wisconsin Medical Society.—At the annual meeting of this society held at Madison, June 26 and 27, the following officers were elected: president, J. M. Evans, Jr., Evansville; first vice-president, John E. Doll, Lake Geneva; second vice-president, J. A. Jackson, Madison; third vice-president, W. H. Palmer, Janesville; fourth vice-president, C. A. Rood, Reedsburg; censors, Carl Kordenat, Reedsburg; S. B. Buckmaster, Janesville, and J. F. Bennett, Beloit; Clarke Gapen, Madison; secretary and treasurer, C. S. Sheldon, Madison.

Philadelphia Academy of Surgery.

June 4, 1900.

Vice-President, Dr. J. R. Harte in the chair.

CYST OF THE THYROID.

Dr. R. G. LeConte reported a case of unilateral cyst of the thyroid, occurring in a man aged 28. It had existed for about four years, constantly became larger, and at last caused pressure symptoms. At the operation, Kocher's angular incision was made, the superficial veins were ligated and the tumor removed. On the tenth day an uneventful recovery was reported.

TUBERCULAR PERITONITIS.

Dr. LeConte also reported a case in which abdominal section was made, with drainage: fecal fistula later developed, necessitating end-to-end anastomosis. The duration of the disease was somewhat indefinite. A large collection of straw-colored fluid developed in the abdomen, which was withdrawn, ninety-four ounces being removed at one time. The blood count showed 5,600,000 red and 50,000 white corpuscles, and later the hemoglobin fell to 57 per cent. Great emaciation was noted, and at one period the patient weighed only sixty-five pounds. The abdomen was opened and drained, but a fistula persisted. This was curetted, a drainage-tube was inserted and gauze packing placed about it. Owing to non-union the wound was again opened several weeks afterward and it was found that a considerable amount of gauze had remained at the site of the operation. An end-to-end anastomosis was done by means of the O'Hara forceps and recovery ensued. In his opinion the presence of the gauze probably aided in the cure, as it ensured drainage.

Dr. G. G. Davis had several years ago operated on a similar case, in which he believed that the introduction of strips of gauze might have been of greater avail than washing with normal saline solution, which had been employed.

EXCISION OF SUPERIOR MAXILLA.

Dr. R. H. Harte reported a case in which he had excised the superior maxilla for a tumor involving that region. The first incision was carried upward from the angle of the jaw to the outer edge of the upper lip, then onward to the opposite side. Another incision followed the inferior maxillary bone, then upward to about the middle of the nose. Recovery ensued on the tenth day.

PERFORATING GASTRIC ULCER.

Dr. Harte reported a case simulating appendicitis, in which the onset was sudden and the patient in a state of collapse on admission to the hospital, with pain in the region of the appendix. The abdomen was hard. At the operation, the appendix was found only slightly abnormal; it was, however, noticed that a large amount of gas escaped on primary incision. The wound was closed but the patient died, and at the autopsy, a perforating gastric ulcer and several other small ulcerated spots were found. Statistics of operations for this condition show a mortality of about 80 per cent.

ANTITOXIN IN TETANUS.

Dr. Addenell Hewson reported a case of tetanus in which antitoxin had been repeatedly used, without effect.

Dr. G. G. Davis believed that the question of the beneficial effects of tetanus antitoxin was still unsettled. He had two years ago reported two cases in which cure had been attributed to this remedy, but lately had lost two of a similar nature, in which the antitoxin had been used.

Dr. W. J. Taylor believed that writers who have reported most cures from the use of antitoxin have generally given the remedy in more or less chronic cases. It is important, therefore, that the type of the disease be specified. In acute cases, he believed that full doses of bromids and chloral, frequently repeated day and night, would be as beneficial as antitoxin. His attention had been called to the tendency for tetanus to develop after injury due to the explosion of fulminating caps, which had been attributed to the character of a certain kind of earth which is usually used in the manufacture of these explosives.

Dr. LeConte had seen six or seven cases of acute tetanus with only one recovery, and in this case full doses [illegible] chloral and bromids had been given.

Colorado State Medical Society.

Thirtieth Annual Convention, Denver, June 19-21.

The following recommendations of the committee on literature for the education of the public with regard to quackery were unanimously adopted:

1. That the Society appropriate the sum of $25 to be awarded in prizes by a committee of three appointed by the incoming president, for the best essays pointing out the dangers to the public health and morals, especially to the youthful members of the community, from quackery as promulgated by public advertisements.

Such essays, if deemed satisfactory to the committee of award and suitable for popular distribution, should be published by said committee of award in one or more medical periodicals, and reprints of same furnished to the members of this Society for gratuitous distribution.

2. That the secretary of the Society send out a circular letter to the editors of all medical periodicals published in the United States, requesting them to publish from time to time, a list of such lay periodicals whose columns are free from advertisements tending to debase and deceive the public.

3. That the Society send the following letter:

The Colorado State Medical Society to the Colorado State Editorial Association, Greeting:—The evident lack of censorship, on the part of the daily and weekly press, of advertisements tending to encourage bestiality, criminal lust and the commission of the crime of abortion, together with the purpose on this Society's part to lessen as far as possible the unhealthful and injurious effect of quackery, especially upon the young, led it to call your attention to the fact of the gross immoral and health-injuring character of advertisements which are accepted for publication by newspapers of to-day. It is assumed that carelessness rather than wilful intent on the part of a calling endowed with higher and nobler purposes is to blame for this state of affairs.

This Society, therefore, respectfully and earnestly recommends and requests that you take up and discuss this matter and establish for objectionable advertisements a limit beyond which newspapers and periodicals represented in your Association can not go and remain in good standing.

Wishing to hear from you on this matter, and assuring you of our cordial desire to aid as we may be able to do in this work, we remain

Yours respectfully,
Colorado State Medical Society.

The election of officers resulted as follows: president, W. P. Munn, Denver; first vice-president, R. F. Graham, Greeley; second vice-president, W. T. Little, Canon City; third vice-president, William Dow, La Junta; corresponding secretary,

H. B. Whitney, Denver; recording secretary, M. C. T. Love, Denver; assistant recording secretary, W. A. Kickland, Denver; treasurer, W. J. Rothwell, Denver; trusteees, J. T. Eskridge, A. Steadman, W. E. Wilson, S. A. Solly, E. J. A. Rogers, H. Works, of Pueblo, J. H. Hall; committee on membership, Drs. S. G. Kahn, of Leadville, C. K Fleming, C. A. Powers, D. F. Dayton.

Chicago Surgical Society.

May 11, 1900.

LIPOMATA.

DR. JOHN E. OWENS reported two cases. The first was that of a woman, who, some years ago, called him to the southern part of the state to operate for appendicitis. There was tumor, pain, nausea and vomiting. The tumor and pain were located in the region of the appendix, and on examination he found a movable mass, slightly tender on pressure. At the time of his visit, the acute symptoms had subsided and she felt fairly well. The attacks were recurrent and quite severe, but were relieved by small doses of salines. Whenever the bowels began to move, the symptoms rapidly disappeared, and in the course of a few days she would be well. She had advanced heart disease, and the cardiac symptoms at each attack were so distressing that she insisted on an operation, although she was informed that she might die on the table. She died about two days after the operation, from cardiac disease. There were no wound complications. The original diagnosis was made in a tentative way. The opinion was expressed that the tumor had too much mobility for an inflamed appendix, and that it was not sufficiently movable for a floating or movable kidney. Being approximately ovoid and about two inches in length, the tumor and its surroundings closely resembled a small kidney, and a concavity, corresponding to the hilus of the kidney, could be felt, and also the outer convex surface, but still the mobility was too slight for a floating kidney. When the operation was performed something was found in the colon just above the ileo-cecal valve, and on opening the bowel, a submucous fatty tumor was discovered. The conditions seemed to be such as to have eventually led to a spontaneous cure, inasmuch as the mucous membrane over the outer parts had ulcerated. It was enucleated and, without stitching the mucous membrane, the bowel was closed in the usual manner. The location of the tumor, as well as its variety, and the diagnosis are points of interest.

The second case, which he saw with Dr. I. N. Danforth, was that of a lady about 60 years of age, who had a large tumor of the thigh, of twenty-five years' growth. It extended from Poupart's ligament to the patella, and apparently involved the whole circumference of the thigh, twenty-nine inches. A shallow depression extended from the popliteal space to the ischium. The tumor was painless, but lately she had found it in the way during walking and sitting so that she was necessarily confined to the house. He first thought it was a cyst, and on Dr. Danforth's inquiry as to what would be done in regard to it, he answered it should be tapped and its contents determined. She was admitted to St. Luke's Hospital and the thigh tapped, with a negative result. He thought that it was a cyst because of its uniform consistency, its slow growth, and the absence of dimpling, so common in fatty tumors. Furthermore he had previously observed, in the case of fatty tumors, the tremulous impulse elicited by striking it with the fingers. This was very evident even when the tumor was struck at one extremity of its long diameter while the hand was applied to the other. This led him to believe that the tumor was a cyst with gelatinous contents, but considering the possibility of the existence of a sarcoma, he made a small opening through the skin, inserted a strong bullet probe and succeeded in reaching the superior surface of the femur. The bone felt natural and smooth. The question of cyst and sarcoma was abandoned and, on dissecting a little further, a lobule of fat presented itself, which made the diagnosis of lipoma clear. The operation was long, as the muscles on the front of the leg were spread over it in several irregular layers, and their fasciculi and aponeuroses so involved with the growth as to render its removal somewhat difficult. The vessels were pushed by the growth inward and downward. The patient made a good recovery.

DR. DANIEL N. EISENDRATH had seen a very interesting case of diffuse symmetrical lipomatosis in a man, who exhibited himself all over Europe. A large fatty tumor was removed from the neck, but returned within six months, behaving apparently like a malignant growth. It is supposed that these tumor have some relation to nerve influence, as they are associated with certain disturbances of the spinal nerve. Dr. Owens' case was interesting, as it in some way resembled a malignant growth pushing aside the muscles and aponeuroses, springing from the intermuscular tissue and invading the surrounding tissue like a malignant tumor. He had looked up the statistics of the weight of the lipomata, and found one recorded which weighed fifty pounds, although tumors weighing over ten are rare. The one removed by Dr. Owens must have weighed about twenty-five pounds.

CHOLECYSTECTOMY AND CHOLECYSTOSTOMY.

DR. ERNEST J. MELLISH discussed these operations and reported cases. The first was cholecystectomy, in a married woman, aged 57; family history negative. Her husband died of gastric carcinoma in 1894. She had always felt well until February, 1899, when she had double lobar pneumonia and was in bed eight weeks. During this time, a firm swelling about the size of a man's fist was for the first time noticed in the right hypochondriac region. It was but slightly tender to pressure. There was neither jaundice, colic, nor any special symptoms indicating disease of a particular organ. She never fully recuperated after this illness, and about the first of August she had severe pain in the lumbar region, radiating down both thighs. At the same time, she began to experience difficulty in stooping and walking, severe pain in the region of the swelling when coughing, and there was progressive emaciation. Diagnosis of chronic, progressive swelling within the abdomen was made by Drs. F. W. Bromley and L. H. Prince, of Palmyra, Wis., and operation advised.

He did not see the patient until the day of the operation, Sept. 16, 1899. She was much emaciated and cachectic, but not jaundiced, the swelling, which seemed as large as a medium-sized cocoanut, produced an elevation of the abdominal wall over it of perhaps 5 cm. above the level of the surrounding surface. The swelling was situated above the colon, was almost unyielding to pressure, and moved very little during respiration, but appeared to be connected with the liver. He thought that the gall-bladder formed a portion of the mass, that it was probably a carcinoma, but might possibly be a case of cholelithiasis. The operation was performed in the Palmyra Springs Sanitarium, under chloroform anesthesia. Exploratory incision was made over the swelling, parallel with the costal margin. On opening the peritoneum, it was found that almost the entire greater omentum was gathered into a mass over the fundus of the gall-bladder, and was firmly adherent to the anterior border and upper surface of the right lobe of the liver and to the parietal peritoneum, so that it was impossible to palpate the gall-bladder. The thick mass of tissue over the gall-bladder was supposed to be carcinomatous. The omentum was tied off in very small sections—a better method than ligation in large masses—as it permits palpation of the lower surfaces of the gall-bladder and the ducts, revealing the presence of large calculi. There were no adhesions on this surface of the gall-bladder below the fundus. The liver was then incised at a safe distance from the swelling—using gauze compresses to control hemorrhage—and the separation completed with the fingers. One of the calculi was wedged into the cystic duct as far as its junction with the common duct. After walling off the peritoneal cavity with gauze, a transverse incision was made over this calculus, which was removed, and the incision across the dilated duct completed. The duct was closed with two rows of Lembert sutures, strips of gauze being passed down to the stump, and packed against the cut surface of the liver, and the abdominal wound closed in separate layers. There was a slight discharge of bile through the drain for a few days, presumably from the cut surface of the liver. Pus formed in the track of the drain; and on the third day, a tubular was substituted for the gauze drain. In a week, the tube was removed and the abdominal wound closed rapidly. For three days the patient hovered between life and death, with adynamic obstruction, although calomel had been given on the first day and no opiate whatever. The temperature and pulse remained near normal; there was no marked tenderness, and the facial expression was not bad. He was convinced that there was no serious infection, though the tympanites increased sufficiently to seriously impede respiration. On the second day she began vomiting; her stomach was washed out, and very small nutrient enemata were administered. Strychnia was given in 1/40 to 1/30 gr. doses every three hours. Large saline and glycerin enemas were given, then enemas of soap and water, turpentin, and, finally, asafetida and olive-oil. The asafetida enemas alone seemd to do any good. The abdomen was firmly compressed with bandages during the whole time as it was markedly tympanitic. Since convalescing from the operation, the patient has been well and able to perform her usual work.

The mass removed was about 10 cm. long, and 5 cm. wide; its long diameter being in the transverse axis of the body, antero-posteriorly. It consisted of the gall-bladder, containing seven calculi and a large mass resembling inflammatory tissue, which included the remains of the omentum. In the mucous membrane of the gall-bladder several irregular ulcers with well-defined, non-indurated margins were found, two or three of which had penetrated nearly to the peritoneal covering of the viscus. A microscopic section made through one of these ulcers at a right angle to its surface, showed round-celled inflammatory infiltration, and, in the deep layers, nests of cells surounded by a connective-tissue stroma, as in carcinoma. The largest of the stones was conical, wedged into the cystic duct, and weighed 6.5 grams; the smallest stone weighed 2.7 gm., and the seven together weighed 27.2 gm. The fact that this patient's husband had had gastric carcinoma might give rise to the suspicion of a common cause in the two cases, although the irritation produced by the calculi, during the many years they must have been in the gall-bladder, might easily lead to malignancy.

Statistics give an average mortality in cholecystectomy of 16 to 18 per cent., due to the operation. This high rate may be attributed largely to the postponement of operations until all become practically emergency operations, as there is no reason why the procedure in itself should be especially dangerous.

When considering cholecystectomy the question arises: Of what use is the gall-bladder to the human economy? There are several theories regarding its function, but no one knows what that is. He is disposed to agree with those who believe that its chief function is to serve the operative surgeon, as it is certainly of so little importance that the economy does not suffer perceptibly when it has been extirpated; consequently it should be removed, if feasible, when in cholelithiasis it is certain that there are no stones in the common duct, and in other conditions of disease confined to the gall-bladder itself, in which there is a strong tendency to chronicity or to cholelithiasis.

There is much variance of opinion regarding the amount of bile secreted in twenty-four hours. Murchison was able to collect but 480 c.c. Some physiologists claim that the daily amount of bile secreted is from one to two times the weight of the liver. The adult liver weighs from 1850 to 2000 grams; the capacity of the normal gall-bladder does not exceed 31 c.c., therefore the function claimed for it, that it is a receptacle for bile between the periods of active digestion, is untenable. Moreover, the gall-bladder is so inelastic that it can not discharge more than 2 to 4 c.c. at a time. The normal gall-bladder is never found empty, and the specific gravity of its contents is always higher than that of the bile in the ducts. Another noteworthy fact is that the gall-bladder secretes in twenty-four hours from 15 to 20 c.c. of fluid of acid reaction, containing no bile salts. The theory that the gall-bladder acts as a controller or governor of the bile circulation in the same manner that the air-chamber acts in a fire-engine to produce a steady, instead of a pulsating, flow, is not supported by any positive evidence. The theory that it is a rudimentary organ, like the vermiform appendix, is not supported by analogy, since the gall-bladder is not relatively much larger in any of the lower animals than in man, and some of them—the elephant, and mouse, for example—have none.

The second case was cholecystostomy in a single female, aged about 45 years, who suffered from menopause neurosis and symptoms of gall-stones, who was referred to me by Dr. Prince. She had had her first attack of colic fifteen or sixteen years before, and for the next ten years had an attack every ten or twelve months. The attacks gradually increased in severity and lasted from twelve to twenty-four hours. About 1894, they became more frequent, occurring every few weeks; and in 1895, she had an attack lasting eighteen hours or more, accompanied by repeated chills and frequent, very watery, black bowel movements, "full of small, black, seed-like particles." From 1896 till 1898, the intervals between attacks became shorter, until the pain returned almost daily, but lasted only six to eight hours. From October, 1898, till March, 1899, She was nearly free from colic, but from that time on the paroxysms occurred every few hours and the pain became steadily worse. During the attacks, there was always some tympanites; and since 1897, tympanites and tenderness were relatively constant features of the attacks. Latterly there was considerable local hyperesthesia, probably due in part to her functional neurosis. As a rule, the bowels were constipated during, and normal between, attacks. The pain was paroxysmal, and up till 1898 it began in the epigastrium, radiating downward and to the right. After this the pain began in the same place, but radiated toward the left shoulder. Jaundice did not occur. For some time before the operation she was in the Palmyra Springs Sanitarium, and fruitless search was made for stones. On May 15, the following operation was performed:

Under chloroform anesthesia an incision was made parallel with the costal margin, the peritoneal cavity packed off with gauze and the gall-bladder opened. It contained bile-stained mucus, but no calculi could be found either in the bladder or the ducts. The mucous membrane of the gall-bladder was very red. The viscus was sutured to the parietal peritoneum and a gauze drain inserted. At the first dressing, tubular drainage was substituted, and for a few days, thick bile-stained mucus was discharged. After this, there was very little discharge, and, in a month, the fistula was allowed to close. No calculi were discharged, either through the fistula or the bowel. The patient had two or three slight attacks afterward, simulating renal colic, but has had none for more than nine months. At the time of operating, the gall-bladder was dilated and the uterus curetted for anteflexion and hyperplastic metritis.

These two cases illustrate that often when we expect to find gall-stones none can be found; and that, on the other hand, we often find them where there have been no special symptoms indicating their presence. Many cases of chronic gastric or gastrointestinal disturbance, without definite symptoms pointing to the liver or gall-bladder, are undoubtedly due to the presence of large calculi in the gall-bladder or cystic duct.

Dr. A. J. Ochsner said that in regard to the second case reported, he had, on several occasions, found it difficult to make a definite differential diagnosis between gall-stone colic and appendicular colic, and had consequently made the incision through the edge of the rectus muscle, about one inch lower than he would in a gall-stone operation. In that way he had been able to palpate the gall-bladder and determine the presence or absence of gall-stones. Through the same opening he had also been able to bring up the appendix for inspection; and had in several of these cases found a fecal concretion in it. This incision had been of service when it was impossible to make a definite differential diagnosis, where the stomach symptoms and the colic were not definite enough to positively indicate the presence of one or the other affection. In palpating the gall-bladder one can not always depend on the sense of touch, because in a certain number of cases there is a variety of sand composed of very sharp particles, resembling uric acid crystals, except that they are black. These particles give rise to just such colics as Dr. Mellish has described. Removing them and draining the gall-bladder for a sufficient length of time to dispose of the inflammation of the lining mucosa, will eventually dispose of the attacks of colic.

MULTIPLE OSTEOMYELITIS AND MULTIPLE PANARTHRITIS.

DR. EDWARD H. OCHSNER reported the case of a boy, 9 years of age, who was referred to him on Nov. 22, 1899, by Dr. Enfield, of Jefferson, Iowa, who had been called in consultation a few days previously.

The family history was negative, with the exception of some indefinite convulsions four years ago, lasting only a few minutes. He had always been well until four weeks before admission, when one morning while at school, he began to feel feverish and had some pain on the inner surface of the right thigh, which seemed to be swollen. He was unable to stand or walk except with considerable pain, and got home with difficulty. On the following day, the temperature rose to 104 F., and he became delirious. The high temperature persisted for two weeks. Three weeks before admission the right elbow became swollen, and one week later the family physician made a small incision into the fluctuating swelling of the thigh and elbow, evacuating considerable seropurulent fluid.

When admitted he was seven pounds under weight; very pale and anemic. The tongue was clean; the bowels were constipated; the temperature was 99.4, the pulse 115, weak and thready; and the heart and lungs were negative. At the left sternocostal junction was a walnut-sized, softish swelling, and in the left axilla another the size of a filbert. The right elbow was markedly swollen and held passively at an angle of 135 degrees; active motion was absent; and the passive, possible about five degrees each way, but beyond this very painful; while rotatory motion was markedly impaired.

The greatest elbow circumference was 26 cm., the middle arm measured 13 cm., and the middle forearm, 11 cm., with points of fluctuation on all sides of the elbow-joint. On the anterior external surface was a pinhead-sized red area where incision was made.

The right leg was held at an angle of 100 degrees; while passively it could be flexed to an angle of 45, and extended to about 135 degrees, and was actively about the same. The thigh was somewhat swollen, and the femur at its middle was markedly thickened. The circumference of the right thigh at the middle was 34 cm., and the left 37 cm.

A probe was introduced into the sinus of the left thigh and passed down to the eroded femur. The incision was made through the skin, then the vastas internus was separated from the rectus by blunt dissection. The lower surface of the femur was found roughened and a portion of the bone slightly eroded. About four ounces of pus was evacuated. The abscess cavity was carefully sponged out and filled with a strong tincture of iodin, which was allowed to remain in about two minutes, then the cavity was packed with iodoform gauze. The secondary sutures were applied and the wound dressed dry.

An incision was made over the olecranon; the triceps, tendon and muscle were separated with blunt dissection from the tendons on the outer surface of the arm. The capsule was then incised and a great quantity of pus evacuated. The ulna was found to be dislocated; and the whole joint cavity was bathed in pus, while the epiphyseal head of the radius was loose in the pus cavity. The joint was carefully sponged dry, treated with strong tincture of iodin and packed with iodin gauze, after the dislocation had beeen carefully reduced. Secondary stitches were taken, and dry dressings used.

The arm was put in an external plaster-of-Paris splint, and placed at a little less than a right angle. A few days later the packing was removed, the secondary stitches tied, and the arm again put in plaster-of-Paris splint. This wound stopped secreting immediately and healed kindly; and the integrity of the joint has been almost completely retained. He has motion in every direction, the flexion is perfect, and the extension nearly so. Internal rotation is perfect, and external quite good, certainly, a much better result than was hoped for at the time of the operation. After a time, the swellings over the sternoclavicular junction, in the left axilla, and of the left knee, subsided under copious wet dressings. The swelling in the left axilla disappeared entirely in the course of a few weeks. After a short, time, however, the abscess in the sternoclavicular junction again increased in size, and on January 15 this had to be opened, when the whole joint was found bathed in pus. It was packed in iodin gauze, and healed kindly. The swelling which previously had been in the synovial sac of the left knee subsided, but on the inner surface of the knee an abscess developed which had to be incised and drained on February 7. Now, all of the wounds have healed except the one over the lower end of the right fmur, where a small sinus remains, leading down to a sequestrum. Except for this, the boy is perfectly well.

The case was presented for the purpose of demonstrating the importance of making an accurate diagnosis. When he was examined a diagnosis was made of pure staphylococcus infection, which was later verified by a bacteriologic examination, and because of this, the elbow was treated just as carefully as if operating on a clean joint. He became convinced long ago that a tubercular joint, or a joint infected with a pure staphylococcus infection, can often be made to heal by primary union if it is not allowed to become infected with other pus micro-organisms or saprophytes.

In tuberculosis, this has long been adopted by most surgeons, at least by those who are successful in treating tubercular joints, and this case helps to prove the contention that if the same care is observed in preventing secondary infection while operating on a panarthritis due to a pure staphylococcus infection, the same ideal results may often be expected.

DR. D. A. K. STEELE said that he had been very much interested in the examination of the elbow of this boy, because of the almost ideal result following the operation for it illustrated so well what can be accomplished by early surgical treatment of these cases. There are few surgeons to-day who believe that when a joint is full of pus it means a loss of that joint. By drainage and proper after-treatment a fairly good result can be obtained. He had known one or two similar elbows that had given equally good results.

DR. A. J. OCHSNER said that he wished to emphasize what had been said regarding the importance of not mixing the microbes, for this holds good no matter whether dealing with staphylococci, tubercle bacilli, or pneumococci. The same is true also of abscesses in bones, due to the presence of typhoid bacilli, a condition which he has been able to demonstrate. He believes that it is important, even if there be a severe infection with one microbe, to keep out all the others.

DR. DANIEL N. EISENDRATH said that he had an experience with mixed or secondary infection that might be of interest. He had been injecting a joint with iodoform glycerin emulsion, and accidentally introduced the bacillus pyocyaneus. He used the Phelps' method of washing out the joint with carbolic acid followed by alcohol and succeeded in completely checking the mixed infection.

DR. JAMES E. MOORE, of Minneapolis, being invited to speak, said that this was one of a class of cases of especial interest and one he liked to have discussed in a surgical society, and also in a medical society, because unfortunately, the average medical man overlooks these cases and usually calls them rheumatism. When a case like this can be operated on and saved, it can readily be understood that the diagnoses should be made at the beginning of the case. Much can be done in the joint of a child, and the younger the child, the better the prognosis. The results may be very good, even after the joint seems to be totally disorganized. When the disease begins outside of the joint, as it often does, it should be prevented from extending into the joint. The question of mixing the germs he regarded as a vital one, bacteriology being indispensable to surgery.

The occurrence of pneumococci in empyema is of considerable importance, as operations for empyema following pneumonia can be performed with the greatest assurance, as recovery will be almost certain. When we have the diplococcus to contend with, the prognosis is invariably good, but when, on the other hand, there is a streptococcus or even the tubercle bacillus to deal with, the prognosis is not so good. ys makes a difference what kind of germs there is fo how badly infected the wound may be in the s germs shall be allowed to be introduced.

SUTURE OF THE MUSCULO-SPIRAL NERVE.

Dr. D. A. K. Steele presented the case of a young man, who, some years ago, while riding his bicycle, collided with the point of a buggy shaft, which struck him on the left arm over the musculospiral nerve, causing a slight laceration of the skin. He went to work the next day, as usual, but found that the arm was helpless. His employer sent him to a physician who, recognizing an injury of the nerve, suggested nerve suture. Another doctor used electricity for about a month with little benefit. Then the young man went back to the first doctor for a while and then suspended treatment for a month or six weeks, finally coming to him. At this time there was a wrist-drop and absolute loss of function of the parts supplied by the musculospiral nerve. On careful examination, he concluded that there had been a lesion of the nerve at the point where the buggy shaft struck the arm. There was absolutely no response to electrical tests. He advised an operation, and performed it three months after the injury. An incision was made directly over the nerve and he found that the ends were separated about three-quarters of an inch, and the space was filled in with connective tissue. An ordinary resection was made, cutting off about one-half inch and securing an end-to-end approximation. The nerve was united with fine interrupted silk sutures, passing through from side to side and from above, downward. The wound was closed up and the arm put in a cast. Primary union followed within a very few days; but there was no restoration of function, the wrist-drop continued, and at the end of two months the operation seemed to have done no good.

At the time of section, a little difference in the color and appearance of the nerve was noticed, but it did not seeem wise to remove any more than one-half inch because of the difficulty of approximating the nerve ends. At the close of two months, a small exceedingly sensitive tumor appeared at the point of operation. A second operation was advised and what proved to be a fibroneuroma, involving the entire thickness of the nerve at the point of the suture was found, the suture being in this mass. The tumor was dissected out and carefully removed, taking also three-quarters of an inch of the continuity of the nerve. Instead of making a square section, a step or stair section above and below was made. By drawing the nerve well up and the upper portion down these mortised parts were laid together and sutures of fine silk were again used. This second operation was followed by prompt union and very slow improvement, but at the end of two months, nothing seemed to have been gained, and at the end of three months, there was but little more improvement. The literature of nerve suture showed that the restoration of function was very slow, so the young man was advised to be patient as nothing could be gained by further operation. He used massage and encouraged the use of his hand, and at the end of four or five months noticed that the drop-wrist was not so bad. The numbness then disappeared somewhat and at the end of six months there was a decided improvement. At the end of eight months, the condition was practically normal, though there was a slight hyperesthesia over the field of operation, and at the point of union, an exceedingly sensitive place, pressure upon which made him wince.

The case was presented because good results following crushing injury of the musculospiral nerve are not very common, and because the first operation was followed by a fibroneuroma, and the restoration of function did not take place until seven months after the second operation, showing that time is an important element in the restoration of function in divided nerves which have been sutured.

Dr. Daniel N. Eisendrath, who was consulted first by this patient, said that he wished to state some interesting clinical points about this case. When first brought to him, twenty-four hours after the injury, the young man simply had an abrasion, without any laceration of the skin, and a wrist-drop. He was examined carefully for areas of anesthesia corresponding to the distribution of the radial nerve, but none were found. He then referred him to a neurologist, who believed that the nerve was contused but not divided. The areas of anesthesia gradually developed, and a diagnosis of actual severance of the nerve was made two months after the injury. Shortly after the first operation, a tumor appeared at the site of the suture which, removed at second operation, proved to be a fibroneuroma with about equal preponderance of nerve and connective-tissue elements. Whether this was in part due to the irritation of the silk was a question, although it seemed to be. The interesting point about this tumor and the lack of success in the first operation was that the nerve was contused above and below the point of resection. This is a frequent reason for lack of success in such operations. Macroscopically, the nerve seemed to be perfect, but microscopically there was seen to be considerable degeneration above and below the injury. The main point in the successful outcome seems to be to distinguish between the amount of superficial and deep injury.

Dr. L. L. McArthur said that at the last meeting he had the pleasure of presenting to the Society a case of suture of the median nerve in which union had occurred and sensibility had been restored within two weeks. He has now planned an operation for resuture of the same nerve in another patient, who, eighteen months ago, received an incised wound of the middle portion of the forearm. He was taken to the County Hospital and the nerve sutured. Sensation returned within three months. It is now eighteen months since the injury, and a little over a year since the suture was made; the man has been unable to follow his trade, that of a tailor, not because of a total loss of sensibility in the fingers, but because of a sense of pain, numbness and tingling. He desires further relief. On examination a very pronounced neurofibroma at the seat of injury was found and he now proposes the removal of that neuroma, and the resuturing of the nerve, though it is possible that no better result may be attained. He asked whether any present had had any experience in the removal of tumors developed in the course of a sutured nerve, or a tumor enucleated without severing the entire nerve, and if such an operation would be feasible and possible. He mentioned a case of double wrist-drop which occurred in one of the tally-ho horn blowers during the World's Fair. While crossing the car-tracks, he was thrown out of his rumble seat, and fell on the back of his head, with his arms thrown backward. A double wrist-drop immediately developed. There seemed to be no injury of the arms, but it was found that he had sustained a traumatism at the level of the fourth and fifth cervical vertebræ. There was tenderness, but no deformity and it seemed that the roots of the fifth cervical nerve had been injured on both sides, causing the double wrist-drop.

Dr. E. J. Mellish said that the question in his mind was whether the tenderness at the point of suture might not be due to the fact that silk was used instead of some absorbent suture material.

Dr. James E. Moore said that in reference to the question asked by Dr. McArthur, he had an interesting case in point. A man of splendid physique had been complaining for a long time of excruciating pains in the region of the perineal nerve. He had been operated on, but without relief, and when he saw him some six months afterward he could distinctly feel a tumor as big as the index finger. He took the precaution to mark the exact location before making the operation, so that he would have no difficulty in locating it. He found he could save a few fibers of the nerve on the inner side, the outer three-fourths being completely destroyed. The man made a complete recovery, and there was not even a temporary loss of motion or function. He had also a case of rupture of the median nerve. The patient came under his care last winter, with a compound dislocation forward of the lower end of the humerus, and a simple fracture of the radius and a multiple compound comminuted fracture of the humerus. After getting the patient under the anesthetic, he concluded to make an effort to save the arm, as the circulation was intact. He could not tell anything about the nerve, but subsequent events showed that it was ruptured. He has now a movable joint, and can pronate and supinate, but has lost the median nerve, which he proposes attempting to restore. The biceps was torn in shreds, making it difficult to restore the function of the nerve on account of the cicatricial tissue around it.

DR. JOHN E. OWENS spoke of being associated with Dr. Gunn in a case of painful tumor of a nerve of the arm, he thought of the musculospiral. Dr. Gunn exposed the nerve at the point of the tumor, separated the nerve fibers and peeled out the mass just as he would an ordinary fatty tumor. The patient recovered perfectly.

DR. STEELE, in closing the discussion, said that the question asked by Dr. McArthur had already been answered. In reference to some of the questions of Dr. Bevan, he fully agreed with him that where there is only a contusion of the nerve the patient should have a chance for several months, as he would probably recover without any operation. In a case of this kind, however, where the patient was given a chance and no improvement resulted, it seemed that sufficient time had elapsed for surgery to step in, and the condition found at the time of the operation proved that an operation was indicated. There was not a contusion, but a complete severing of the nerve. The upper end was bulbous and the lower end was small and separated for about one-half inch. Very little evidence was given externally of the severity of the injury, as there was only an abrasion. With reference to the cases of paralysis following fractures with injury of the musculospiral nerve, he said that many of them are due to the pinching of the nerve by the formation of callus, and the embedding of the nerve in the mass. As this contracts or ossifies it gives rise to severe pain, which must be relieved. These cases will probably improve, as the callus is absorbed, but if not, or if the pain is extremely severe, the callus must be chiseled away. The tenderness or hyperesthesia now present may be due to the fine silk suture used, and it is quite possible that it was responsible for the first neuroma, but we must remember that in suturing a nerve or tendon, a material with considerable tensile strength must be used.

Proceedings Wisconsin State Medical Society.

Fifty-Fourth Annual Meeting, Milwaukee, June 20-22, 1900.

UNUSUAL MANIFESTATIONS OF MALIGNANT DISEASE.

Dr. C. W. Oviat read a paper having this title. It was discussed by Dr. G. A. Kletzsch and Dr. A. J. Burgess, of Milwaukee. The latter deprecated the importance given to age as a factor in diagnosis. It usually ought to be excluded, not only in the diagnosis of the disease in question, but generally, as it is misleading and a stumbling-block.

CANCER OF THE UTERUS.

DR. G. A. KLETZSCH read a paper on this subject. Dr. Herman Reineking, of Sheboygan, in discussing the pathologic side of the question, stated that in his opinion the similarity of the proliferation of cancer to that of syphilis and tuberculosis indicated a bacterial origin of the disease.

DR. A. J. PULS, of Milwaukee, discussed the subject of surgical treatment of cancer of the uterus. The failure of a vast majority of operations for cancer of the uterus to effect a cure, he said, was due to the fact that the cancerous infiltration extended much more deeply than was commonly believed, and was really found in what is supposed to be healthy tissue. He recommended the new operation of Dr. Kelly, described in the issue of the JOURNAL of May 19, 1900.

DR. J. W. COON, of the health department of Milwaukee, gave figures showing that cancer in general, including cancer of the uterus, is increasing in the United States with alarming rapidity.

DR. EMIL RIES,of Chicago, by invitation, closed the discussion. He opposed the Kelly operation described by Dr. Puls, for the reason that it would result in the infection of healthy tissue during and by the operation, and recommended the operation which he had himself first suggested, but which was first performed by Dr. Clark, and which is known in the United States as the Clark operation, and in Europe as the Clark or Ries operation, this operation having for its object the removal of all structures that could possibly be affected, and being therefore much more successful than other operations. Dr. Ries claimed that the cancerous tissue is much more extensive in its infiltrations than is generally thought. The reason for the general belief is that frequent examinations with the microscope do not show the cancerous structure; but if hundreds and hundreds of sections are made and examined, the cancerous structure may be found, and if one of these sections indicates the presence of the disease, that, of course, determines that the disease has extended as far as the tissue in question.

A PLEA FOR THE UNBORN.

DR. EDWARD EVANS, of LaCrosse, in his paper on this subject, attacked abortionists and deplored the prevalence of the crime. He stated that our birth-rate is only 2 per cent. higher than that of France.

MR. JOHN T. KELLEY, of Milwaukee, discussed the question from a legal standpoint. In most of the states the degree of the crime does not depend on the time of performing the abortion.

DR. G. J. KAUMHEIMER, of Milwaukee, scored the daily press, which, almost without exception, shamelessly flaunts the advertisements of professional abortionists in the face of the community. The consensus of opinion was that the remedy for the evil lay in the direction of moral education rather than to obtain nearly impossible convictions under the law.

SUPPURATIVE OTITIS MEDIA.

DR. H. V. WÜRDEMANN, of Milwaukee, read a paper on suppurative otitis media in children. He protested against the culpable ignorance of people in general in not recognizing the serious importance to life of prompt treatment of cases of inflammation within the ear. The diagnosis of otitis media is so easy, and the treatment is so simple, that every physician should be as expert in its diagnosis and treatment as the specialist. Paracentesis is usually advisable.

INFANT FEEDING.

DR. L. BOORSE, Milwaukee, read a paper on the present status of substitute infant feeding, with special reference to the percentage method, and home modification of cow's milk. Pasteurized milk, when fresh and properly protected from contamination, remains practically sterile for a sufficient length of time to render it safe for infant feeding. The advantages of the percentage method over former methods now in general use are generally recognized and earnestly recommended. The best results in substitute feeding are obtained in asepsis and adaptation to the digestive powers of the individual.

DR. J. NOER, of Stoughton, read a paper on substitute infant feeding in general practice. He said that the problem was simple until 1890. Proprietary infant foods are to be condemned as absolutely unreliable and inadequate in their constituents. They should not be used except as a last resort or a temporary expedient when good dairy milk can not be obtained or tolerated. This, however, does not apply to some of the latest German products. Clinically tested these milks have all failed. It is difficult to explain why scientific laboratory milk mixtures are unsatisfactory substitutes, leading to malnutrition, etc. Laboratory milk in the hands of experts is a success in 5 per cent., a partial success in 9 per cent., and a total failure in 65 per cent. of all cases. It does not solve the problem of substitute infant feeding. The filth brought in milk into our homes is terrible to contemplate. It is estimated that 300 pounds of cows' excrement are furnished to New Yorkers each morning. An examination of ordinary, uninspected milk as sold, shows the presence of bacteria varying in numbers from 100,000 to 30,000,000 per cubic centimeter, as compared with an average of 1,000,000 bacteria per cubic centimenter found in the average specimen of sewage. It is to be considered that many of the bacteria found in milk are non-pathogenic. The problem is to obtain pure, uncontaminated dairy milk for infant feeding. This problem seems to be solved by the Copenhagen plan of supervision and inspection.

DR. H. B. SEARS, of Beaver Dam, in discussing the subject, called attention to the fact that the bacteria present are almost entirely in the cream, and therefore that cream should never be used without sterilization. Sterilization, however, does not materially improve the toxins and filth. Some authorities hold that if the milk be deprived of its animal heat immediately and reduced to a temperature of about 40 degrees, it will be comparatively germ-free.

SCARLET FEVER.

Dr. F. D. Miller, of Milwaukee, read a paper on the subject of scarlet fever. He gave a complete history of the disease. Atypical cases occur which are sometimes difficult of diagnosis.

Dr. J. J. McGovern, of Milwaukee, said that the disease he thought was not transmitted by air nor by the scale of desquamation. Certain cities and localities are apparently immune. The disease seldom occurs in the South. It rarely occurs in Paris, but is quite common in Berlin.

Dr. F. A. Kleinhans, of Milwaukee, said that it was certain that scarlet fever could recur in the same patient; also that the cause of the disease was unknown.

Dr. H. B. Sears, of Beaver Dam, advised the use of the bath to reduce temperature.

Dr. Kaumheimer advised that the urine be examined frequently for a period of at least six weeks after the patient is apparently well, in order to guard against an attack of nephritis. He said that he knew of recurrent cases where the diagnosis was undoubted.

Dr. Juergens, of Fredonia, advised the use of the pack where a bath-tub was not available.

CHLORETONE.

Dr. W. B. Hill, of Milwaukee, read a paper on chloretone, a new hypnotic. He said that it was the ideal local anesthetic, being germicidal and antiseptic and having no after effects. It can be used with perfect safety even in very large doses and is never contraindicated.

The paper was freely discussed and the weight of opinion was most favorable to the use of the drug both as a general and as a local anesthetic; and especial reference was made to its use in cases of nervous insomnia.

ANNUAL ADDRESS; CARDIAC AND CIRCULATORY DISEASES.

The annual address in medicine was delivered by Prof. Alfred Stengel, of Philadelphia. The speaker paid especial attention to cardiac and circulatory diseases and laid stress on the importance of close attention to the symptoms of these disorders. This class of diseases is increasing, but the increase is probably due to the increased length of life lately obtaining. Cases of myocardiac disease were described, and the necessity of careful study of that condition emphasized. Any case of heart irregularity in a man past 40 should not be regarded as functional unless it is clearly shown to be such, but myocarditis should be suspected.

RHEUMATOID ARTHRITIS.

Dr. W. H. Neilson, in his paper on rheumatoid arthritis, said that the origin of the disease is probably infectious, and that it must be carefully differentiated from rheumatism. The prognosis is not good for cure, but is good for amelioration.

Dr. W. H. Washburn, of Milwaukee, in discussing the paper, showed that the origin of the disease was bacterial and not nervous. The damage that the disease has done can not be repaired, but the disease can be checked.

Dr. W. G. Kemper, Manitowoc, said that the disease was obstinate to treatment, but described proper course of treatment viz,, change of climate if necessary, hygienic surroundings, use of eliminatives and drugs. Treatment must be long continued. The fact that patients suffering from this disease are not subject to tuberculosis would suggest serum treatment.

SURGICAL TREATMENT OF EMPYEMA.

Dr. W. A. Batchelor, Milwaukee, presented a paper on the surgical treatment of empyema and purulent pericarditis. He said that incision and drainage are the proper means of treatment. He described Hippocrates' treatment, and showed its remarkable similarity to the modern method. He advised rib resection, but discouraged irrigation.

Dr. F. Shimonek, Milwaukee, held that early resection even in children is almost always advisable, and stated that secondary resection is a very difficult operation.

Dr. Herman Reineking, Sheboygan, spoke in favor of irrigation. There was quite a difference of opinion regarding the advisability of universal early resection.

RADICAL CURE OF HERNIA.

Dr. H. A. Sifton, Milwaukee, read a paper on the subject of the radical cure of hernia. He said that catgut and kangaroo tendon sutures, although not ideal, are better than non-absorbable sutures. The operation is one of the most frequent of major operations and the results are most gratifying.

ANNUAL ADDRESS ON SURGERY.

Prof. Maurice R. Richardson, Boston, then read the annual address in surgery, on the subject of conservatism in surgery. In regard to appendicitis he said that the first pain experienced was frequently caused by rupture. In the treatment of acute appendicitis radicalism shold be employed at the earliest possible period. The appendix should be removed because it is a useless organ, and there is everything to gain and nothing to lose by its removal. Gall-stones and tumors should also be attacked at the earliest possible moment. Early recognition and early operation should be our watchword. In all these diseases the fatality is due to the condition and not to the operation. Surgery of the ovary is, however, pre-eminently a field for conservatism unless malignancy is present.

Dr. F. Shimonek, Milwaukee, then read a paper on primary branchiogenic carcinoma.

Dr C. G. Wilson, Milwaukee, read a paper on Addison's disease.

Dr. W. G. Kemper, Manitowoc, read a paper on the essentials of life and longevity. He said: Many of the theories of medicine to-day are preposterous. In rummaging for panaceas we overlook the real root of our complications. The simpler and more primitive the civilization or condition of life, the healthier the people. Inherited morbid proclivities may be overcome by long-continued observations of hygienic principles. Every person should drink at least four pints of water daily. "Live on a shilling a day and earn it." Following these rules disease will ultimately be eliminated and men will sink into their final slumber in old age painlessly.

Dr. Byron Robinson, Chicago, spoke regarding 250 vaginal hysterectomies done either by himself or under his supervision. He considers the vaginal route preferable in all cases to the abdominal route. Hernia does not follow the vaginal operation; the death-rate is only 4 per cent., and this will be decreased.

Dr. F. H. Edsall, Madison, read a paper on the subject of the relationship between ocular affections and systemic diseases.

Dr. C. Zimmermann, Milwaukee, read a paper on cholesteatoma of the middle ear, and its radical treatment. He said that the disease might continue for many years without disturbing the general health of the patient. He described operation, but claimed that this is only the commencement of the treatment, and that the disease has a great tendency to relapse.

THE COUNTY ASYLUMS OF WISCONSIN.

Dr. Richard Dewey, Wauwatosa, read a paper on the county asylums of Wisconsin from a medical standpoint. Dr. Dewey criticized the county system, while admitting that its modification as found in Wisconsin was the best example of that method of caring for the insane. The county asylums are as a rule run too cheaply. Proper medical attention is not given to patients in all cases, for the reason that most of the superintendents of county asylums are not physicians.

Dr. W. A. Gordon, Winnebago, said that it was not quite correct to say that Wisconsin had the pure county asylum plan in operation, for the reason that all such asylums are under state control. One great advantage of county asylums over state asylums is derived from their publicity. Friends can much more readily, frequently and at less expense visit the patients than in the case of state institutions.

Dr. A. J. Burgess, Milwaukee, condemned the county system on the ground that the patients did not receive proper medical treatment, proper care or sufficient food.

Dr. G. A. Kletzsch, Milwaukee, called attention to the excellence of the Milwaukee County asylums.

THE USE AND ABUSE OF THE GALVANOCAUTERY.

Dr. C. D. Conkey, Superior, read a paper on "The Use and Abuse of the Galvanocautery in Nasal Surgery." The speaker said that the objections raised against the cautery are founded upon its improper use. As a matter of routine practice it should not be used behind the roof of the nose, the middle turbinated, the vault of the pharynx, the soft palate and the uvula, and upon the septum, only when much hypertrophied or deeply congested, and then the burn should be neither deep nor extensive. Upon the lower turbinated it may be used to great advantage, confining the applications as much as possible to thrusts, and avoiding large electrodes. In the throat it may be used to the greatest advantage, upon the tonsils, pharyngeal hypertrophies and follicles, and at the base of the tongue to destroy dilated blood-vessels and hypertrophied glandular tissue, but using it so as to avoid contact with the epiglottis.

PRESIDENT'S ANNUAL ADDRESS.

Dr. W. T. Sarles, Sparta, delivered the president's annual address. He dwelt upon the fact that this is the day of the specialist. He thought the society should be divided into sections; that there should be two grand divisions, one of surgery and one of medicine, which would listen to papers by great specialists. He was convinced that the physician should exercise his duties of citizenship more extensively than he does. Not until we have more of these men in the halls of Congress will we obtain a national health commission and corresponding laws. The chief aim of the medical practitioner is to do good.

The following resolution was adopted:

The president shall annually nominate a committee of one on national legislation, who shall act with the permanent committee on legislation of the American Medical Association and who shall meet with said committee of the Association once each year in Washington, D. C.

Two hundred dollars was appropriated for the use of the legislative committee.

A committee of five is to be appointed to work out the problem of having a pathologic exhibit which can be used for the American Medical Association meeting.

The following resolution was adopted unanimously:

That the constitution be amended to read that the annual meeting shall be in May or June, subject to the call of the president, secretary and executive board.

Dr. J. F. Pritchard, Manitowoc, was elected president; Dr. H. V. Würdemann, Milwaukee, first vice-president; Dr. Edward Evans, La Crosse, second vice-president, and Dr. George M. Steele, censor.

Waukesha was chosen as the place of meeting for the next convention.

AMERICAN.

2. **Antivivisection.**—Ernst's paper shows the fallacies and misstatements of the antivivisectionists.

3. **The Law of Dying Declarations.**—Sughrue gives the Massachusetts law of dying declarations, which make an exception to the rule that the defendant has the right to be present and cross-examine the witness. The reason for this is the presumed solemnity of the occasion and thus it is essential that they should be made while the patient is *in extremis* and thoroughly conscious of his condition. The statements must be relative to a crime, and descriptive of the crime itself, and of the person committing it. The form is indifferent; it may be oral or written. The cases in which they are admissible are regulated by the Massachusetts statute, and include those of homicide and abortion. They are only admissible when the death of the declarant is the subject of the inquiry. The jury have the right to consider all the circumstances under which the declaration was made and the state of mind, as shown by the testimony.

5. **Marks Produced by Pistol Shots.**—Hough gives the results of experiments made by him to show the marks produced by pistol shots at various distances. He used white blotting-paper, which he considered took about the same amount of powder mark as the human skin. He found that it is not possible to determine with absolute accuracy, from the mark alone what is the caliber of the weapon used or the distance from which it is fired. If the mark is a smut without tattoo the shot was fired at a distance not over 6 inches; if the mark consists of a tattoo with distinct smut at the center, then the distance was not over 2 feet; if the mark consists of a bullet-hole alone, the range was not less than 4 to 6 feet, if a 22-caliber was used; 7 to 9 if a 32, and 9 to 12 if a 38 or 41.

6.—See abstract in The Journal, xxxiii, 1615.

9. **Perimetric Diagnosis.**—Sherer's article gives a résumé of the facts as regards pathologic restrictions of the visual field and their conditions and lesions underlying them.

10. **Pneumatic Cabinet in Phthisis.**—De Vries describes a pneumatic cabinet devised by Dr. Williams, of Brooklyn, N. Y., which had the approval of the late Prof. A. L. Loomis as a valuable aid for the control of phthisis. He describes the apparatus and claims that it produces a much greater inflation of the lungs than is possible by the ordinary full inspiration, and thus increases pulmonary circulation and lymphatic absorption. When the patient is seated in the cabinet, while gradual rarefaction is made, the entire cutaneous and pulmonary pressure is diminished, the respiration is easier, and the vessels are dilated all over the body, though chiefly in the lungs, thus slowing the circulation at all points, and causing pulmonary congestion, which is developed in precisely the same way as in high altitudes, but differing from that following inhalation of rarefied air, in being modified by the dilatation of the cutaneous vessels. In placing the tube in his mouth, an action of the lungs is produced which removes the debris. He has found it exceedingly advantageous in hemorrhagic cases and in advanced stages of the disease. In the early stages, it is capable of doing much good, often arresting the morbid process. He considers it valuable in strengthening and developing weak and imperfectly developed lungs; and in the latter stages where cure is impossible, it prolongs life with comparative comfort. He suggests the tracheal injection in addition to the cabinet treatment, and thinks that it has been a valuable, though neglected, therapeutic agent.

11. **Tuberculin Test in Diagnosis.**—Anders favors the use of the tuberculin test for the early recognition of pulmonary tuberculosis, and claims that when properly used it is absolutely free from danger. He thinks that if its diagnostic value could be separated in men's minds from its therapeutic use many objections would be removed. It should not be employed in doses of more than .5 milligram at the beginning; after the lapse of a few days the injection may be repeated in larger dose.

13.—See THE JOURNAL of June 23, p. 1589.

14. **Obstetrics in Private Practice.**—Cooke thinks it necessary that a careful history should be kept of every case from the time it is first seen till the end of the puerperium. He uses cards, which are filled out, one for pregnancy, one for the labor, and one for the after-treatment; on these cards every detail is recorded and they are then filed for future reference. For examination of the urine, he has adopted the following plan: A number of wide-mouthed, glass-stoppered bottles are provided with labels having these details—take specimen from mixed evening and morning urine and deliver before noon on specified date; amount for twenty-four hours; name, address, and date. In this way, he has all his urine examinations come in at one time. He has also provided himself with a number of wooden boxes containing bottles of distilled water and boric-acid solution, which he sends out to patients three weeks before labor is expected, so that it may be on hand for the needs of the case. Boiled water can always be had, but is not always available as promptly as required. He has given up the idea of having a sterilized obstetric bag and prefers to have his materials so that they can be sterilized on the spot if necessary; when needed they can be cooled with the distilled water which is at hand. In this way, he is independent of his outfit, and is prepared to go from one case to another without any lengthy sterilizing between.

16. **Scarlatina.**—Class reports experiments with cultures of the diplococci described by him as connected with scarlatina, and tests with serum obtained from inoculated animals. His results are not, as he admits, conclusive as regards the future of serumtherapy of this disease, but he maintains his belief as to the specific nature of the organism.

17. **Exophthalmic Goiter.**—The general conclusion reached by Gordon in this article is that exophthalmic goiter is a disease of the nervous system associated with a pathologic condition of the sympathetic nerves. He tabulates a number of cases of medical and surgical treatment of the thyroid and operations on the cervical portion of the sympathetic nerve as favoring his views. He lays down the therapeutic indications as follows: 1. If the syndrome of the disease is the result of a mechanical pressure on the sympathetic nerve—tumor or thyroid gland, etc.—remove the pressure, and if the symptoms persist, operate on the sympathetic. 2. If the syndrome of the disease is the result of reflex influence on the medulla and through the last on the sympathetic nerve from some remote affection, as fibroid uterine tumors, nasal polyps, etc., remove the last, and if the symptoms persist, operate on the sympathetic nerve. 3. If the syndrome of the disease occurs during the course of any spinal or other organic nervous disease, abstain from operation. 4. If there is no apparent cause, operate on the sympathetic nerve. At any rate, never operate on the hypertrophied thyroid gland. Medical treatment can be used, if the patient refuses an operation, but never expect any permanent cure or entire removal of the symptoms.

18. **Gastro-Intestinal Disorders.**—Bettman reports cases of chronic diarrhea associated with impaction of long standing, or scybala in the colon simulating gastric ulcer; and obstinate constipation with pain relieved by laxatives; also rectal trouble; internal hemorrhoids; and gastric catarrh simulating other conditions. He thinks that gall-stones may also start various forms of gastric disturbances, their diagnosis sometimes being decidedly obscure.

21. **Washing the Bladder.**—Fluhrer's apparatus, which is described in full, is designed to meet the indications for thoroughly washing out the bladder. Two conditions must be realized: the bladder must be in a state of comparative rest in any given capacity of contents during the procedure, and while thus at rest the contents must be more or less agitated. It is important to have an antiseptic impression as thorough as possible without causing irritation, and this apparatus is intended to give complete control over the irrigation.

22. **Impactions in External Auditory Canal.**—About 10 to 12 per cent. of all cases in ear clinics, according to Roosa and Burkner, are those of impacted plugs in the external ear. Four kinds are described. The first and most frequent form is inspissated secretion of the ceruminous and sebaceous glands, lining the canal. These may be of long standing and of considerable hardness. The second form is composed principally of epithelial scales due to chronic desquamative dermatitis of the external auditory canal. This is of a grayish or pearlish hue, usually not so smooth as the ceruminous plug, and is removed with considerable difficulty. The third variety is cholesteatoma, showing through the speculum as a pearly-gray mass. It originates usually in the mastoid cells and works its way toward the meatus, or originates in the canal and erodes toward the mastoid. It may complicate the epithelial plug and vice versa. Absorption of the bone may proceed to such an extent as to enlarge the canal so that the finger can be pushed down to the drum. The drum membrane is rarely injured, but the bone readily yields and the growth finds its way into the mastoid; and, unless completely removed, the case may end fatally, through mastoid involvement and its consequences. The fourth variety is associated with chronic suppuration and perforation, and consists of a hard, grayish, ill-odorous plug of dried pus, wax, epithelial cells, etc. It may lead to serious trouble. The simple ceruminous plugs are usually harmless though they may cause chronic dry otitis. The symptoms are sudden deafness, dizziness, pharyngitis, and in rare cases, paralysis, melancholia, reflex cough and bronchitis. Sometimes the hearing may even be improved for a time, while in some instances the brain symptoms have led to serious errors in diagnosis, a case of convulsions and coma being recorded as due to this cause. The objective symptoms are the described mass in the meatus as seen through the speculum; the ceruminous plug being a black or brownish-yellow mass. The tuning-fork applied to the forehead or teeth is heard with exaggerated loudness in the ear containing the impaction. The patient may complain of deafness coming on suddenly, a fulness of the ear or dizziness, and the tuning-fork symptom mentioned may be present. In these cases, restoration of hear-

ing is only complete in from 30 to 40 per cent. The treatment recommended is mild syringing with warm water; the curette, as recommended by Buck, not being safe except in the hands of the skilled specialist. Extreme gentleness of manipulation and absolute antisepsis are essential; and after the removal of the occlusion syringing should be done with great caution. In some cases, it is necessary to soften the plug by a saturated solution of bicarbonate of sodium, a 2 per cent. solution of carbonate of potassium in equal parts of glycerin and water, dropped into the ear, warm, 5 to 10 drops, three to four times a day. This will soften the plug in a couple of days so that it can easily be removed. The use of olive-oil in the ear should be absolutely discountenanced as it favors the growth of the aspergillus. The tendency to recurrence is a characteristic of ceruminous accumulations, and is due to a hyperactivity of the secretory glands. It is therefore advisable to instruct the patient to wash the ear thoroughly, once a week, with a mild alkaline solution—1 dram of aqua ammonia to a quart of warm water—and castile soap. He insists on the importance of some knowledge of otology by the general practitioner.

23. **Soil Dampness and Tuberculosis.**—Newton discusses the subject of soil as related to tuberculosis and insists that this factor is of greater importance than milk and other matters that have been so much discussed of late. He thinks that it would be better to turn attention to the altering of the surroundings of patients and curing them of their vicious methods of life, instead of trying to annihilate the tubercle bacillus.

30. **Colonial Treatment of Epilepsy.**—Brower's paper is largely historical, reviewing what has been done in the colonial treatment of epileptics in this country and abroad. He suggests the need of such an institution for Illinois and the plan on which it should be established.

31. **Maternal Impressions.**—The common belief in maternal impressions is noticed by McCutchon, who reports a case which seems to him unique. A newly-married woman, brunette, with her husband, who is also dark, saw an albino in a museum, who interested her very much. Nine months later she was delivered of a normal child, still-born; and again in eleven months, of a well-developed boy, who was a perfect albino. The third child was a boy with black hair, but with blue eyes like the first. The fourth was a perfect albino, the fifth and sixth were anecephalous albinos, the seventh was normal, the eighth, ninth, tenth and eleventh were albinos. There seemed to have been a tendency to abnormal births in a collateral branch of the family; and the patient's eldest sister was born deformed. The author quotes Dabney's conclusions in regard to maternal impressions, as published in Keating's "Cyclopedia on Diseases of Children." See also title 103.

35.—See abstract in The Journal of June 9, p. 1486.

37.—See title 117 in The Journal of June 23, p. 1649.

66. **Toxemia of Pregnancy.**—Grandin discusses this condition and points out that it is a grave error to test the urine of a pregnant woman for albuminuria alone. Toxemia may exist with very slight albuminuria or a larger amount of albuminuria may be significant of no serious condition. If there is a tendency to nephritis, the pregnant woman should be watched with great care, and where, notwithstanding regulated diet, etc., the urea and amount of urine diminishes, the question of arrested gestation should be seriously considered. When the eclampsia is imminent or present the sheet-anchor of treatment should be rapid evacuation of the uterus and, as a rule, venesection, and protracted irrigation of the colon with hot saline solution. Morphin is contraindicated, as is also ether. The effect of chloroform is temporary. Several cases are reported illustrating these views. He thinks the only justifiable treatment of toxemia is the surgical, before active manifestations appear. The latter part of his paper is given to the discussion of the operative treatment of uterine displacement. He thinks that uterine suspension meets his ideal more nearly than any other. He describes his method of operating, which he has employed in fifty or sixty cases.

67.—See abstract in The Journal of May 26, p. 1337.

68. **Ectopic Gestation.**—The treatment of full-term ectopic gestation is discussed by Cragin with reference to the endeavor to save the living child. He reports cases illustrating his views, and concludes from study and experiments that: The viable ectopic fetus is worth saving; that attempts to save the child do not seriously increase the mortality or morbidity of the mother; and that in the treatment of full-term ectopic gestation the child should receive more consideration than it does at present.

71.—See abstract in The Journal of May 26, p. 1338.

72. **Infarcts of the Placenta.**—This paper by Williams is accompanied by a very full bibliography. He says that infarcts measuring at least 1 cm. in diameter were observed in 63 per cent., while smaller ones were noticed in a great majority of cases, and microscopic examinations revealed early stages of their formation in every full-term placenta. The primary cause of these formations in a great majority of cases is found in the endarteritis of the vessels of the chorionic villi, the primary result of which is coagulation necrosis with a subsequent formation of canalized fibrin. The part played by the decidua in the production of infarcts has been greatly overestimated. It is more than probable, in a number of cases at least, that the tissue called decidual is really fetal ectoderm. Moderate degrees of infarction have no pathologic significance and are to be regarded simply as signs of the senility of the placenta, analogous to changes in the villi. When marked infarct formation occurs, however, it often results in death or imperfect development of the child It is usually associated with albuminuria on the part of the mother, though the relation existing between these conditions is not clear. They are not particularly observed in acute eclampsia unless they are preceded by decidedly albuminuric symptoms. There is no evidence of their bacterial origin.

75.—See abstract in The Journal of May 26, p. 1337.

82. **Treatment of Epilepsy.**—The general broad principles laid down by Spratling are summarized by him as follows: 1. Make an early differentiation of the type of epilepsy from which the patient is suffering. 2. If it is reflex epilepsy, or if the child is suffering from epileptic phenomena, the chances of cure are much greater than if the case is one of genuine epilepsy. 3. If genuine epilepsy is present, a much more accurate prognosis as to the ultimate outcome may be given and better principles applied in the treatment of the case. 4. Remove, as far as possible, parental sympathy from the treatment of the child for if allowed to assert its way this usually does more harm than good. 5. Endeavor to keep from the young epileptic the many patent nostrums that, when taken, only aggravate the disease by first masking the true symptoms, then destroying or impairing the functions of the gastrointestinal tract. 6. If the seizures are localized and a certain part of the body is chiefly involved at the time of convulsive phenomena, and exhaustion or partial paralysis is the result, apply physical means for its correction as soon as possible, for it is only by these means that such a difficulty can be overcome. 7. Learn to place great value on little things in studying the etiology and treatment of this obstinate malady. In illustration of the last point he told of a visit in January of the present year, to the Pathological Museum, in Berlin, under direction of Dr. Rudolph Virchow, where he saw six cases in which the hemorrhage had occurred in a capillary form in the brain. Dr. Virchow, without the use of any magnifying power, had no difficulty in locating the seats of these minute hemorrhages. He found that these with their results had caused death.

91. **Plantar Reflex.**—Walton and Paul have investigated the plantar reflex in a large number of cases, including 200 hemiplegics and diplegics, old and new; 30 cases of spinal

pyramidal disease; 70 infants, and 400 cases in which no recognized lesion of the pyramidal tract existed; and 100 cases taken at random from hospital patients outside the neurologic department. Their investigations confirm the importance attributed to the symptom by Babinski. They find that in health it may produce either flexion of all the toes or some of them, generally the outer; flexion of all the toes on one side, and of some, generally the outer, on the other; entire absence of movement on both sides in about 10 per cent.; flexion of all or some of the toes on one side with absence of movement on the other in at least 10 per cent., also, occasionally, in sensitive individuals, quick irregular movements, sometimes of flexion and sometimes of extension. In early infancy, no constant or characteristic movements of the toes appear, though extension is rather more frequent. The Babinski reflex occurs in about 70 per cent. of hemiplegics and diplegics, and in approximately the same percentage of cases of pyramidal tract disease of the spinal cord. The Babinski symptom —deliberate and constant extension of the great toe, with or without extension of the others—is never present in health; and other observations make its existence doubtful in either functional or organic nervous diseases not implicating the pyramidal tract. It is often the earliest to appear in pyramidal-tract disease, before the exaggerated knee-jerk and ankle-clonus and it may persist after other reflexes are absent. It is therefore a most important practical diagnostic point. This reflex very exceptionally appears in cases not conforming to recognized types of pyramidal disease—meningitis, hydrocephalus, poisoning, as by alcohol or uremia. Such instances are too few to materially impair the diagnostic value of the phenomenon. It should suggest pyramidal involvement possibly by edema or indirect pressure.

92.—See abstract in The Journal of February 27, p. 430.

98. **Tuberculous Peritonitis.**—Caille reports a number of cases of tuberculous peritonitis in which the first diagnosis was based on the abdominal symptoms, such as distension, pain, bowel disturbances, presence of fluid, and loss of weight; and was made by exclusion, excepting in those cases where the tubercle bacilli were found. In all a febrile rise in the temperature of the irregular type was met. The tuberculin test was employed in two cases, one with positive and the other with negative results; but he is unwilling to make a routine test with tuberculin in the present unsatisfactory state of our knowledge. He adds a fourth variety of tuberculous peritonitis to the three other classes, i e., tuberculous peritoneal tumors, two cases of which have been seen by him. The cases reported show the futility of medicinal treatment, and where such seems to succeed it should not be forgotten that spontaneous cures of this condition have been observed. The indication in all cases is early operation but that it will produce a complete cure is somewhat doubtful; and if there is also lung implication, the ultimate results are unsatisfactory.

103.—See also ¶ 31.

109. **Gonococcus.**—Young reports successful cultivation of gonococcus in chronic cystitis, pyonephrosis and peritonitis, thus adding three conditions to those already known to be due to the gonococcus. He discusses these cases and claims that they are more conclusive than those already published.

110. **Exfoliation of the Lips.**—Stelwagon reports two cases of persistent chronic exfoliation of the lips, both essentially the same disease, though one was more pronounced than the other. He considers the condition as allied to eczema seborrheicum, and is strongly impressed with its parasitic character. Bacteriologic examination of the second case was made at the laboratory of the Jefferson Medical College and several organisms were found, cocci and bacilli, and one indistinguishable from saccharomyces albicans. The treatment was not especially successful in one case, but in the second it seemed to hold the disease somewhat in abeyance. The method consisted in painting with salicylated tincture of benzoin and myrrh and silver nitrate solution, tincture of iodin, and ichthyol. Finally, lactic acid was employed, and, while the reaction was severe, the results were apparently rather favorable.

114.—See abstract in The Journal of May 26, p. 1338.

115. **Anatomy of Reflexa in Ectopic Pregnancy.**—This condition is described by Couvelaire from a study of specimens, and he sums up his results with the statement that there exists in the gravid tube during the first months a membrane, which limits the free pole of the ovum and acts as a reflexa. At the level of this reflexa, chorial villosities and intervillous space are as much developed sixty-six days after the last menses as at the level of the parietal insertion of the ovum. A little later—about 2½ months—there is atrophy of this reflexa by means of thrombosis of the umbilical vessels, and atrophic degeneration of the villosities throughout nearly its entire extent. The membrane which divides the intervillous space of the tubal cavity of the free pole of the ovum is made up of two distinct layers; the first, an internal continuous layer, the compact cellular layer of the reflexa, which is formed by large living cells grouped in a solid mass, lodged in alveoli of an amorphous intercellular stroma, analogous to the fibrin streak of the uterine ovum. These are in continuous relation with the epithelial process and a certain part of them are undergoing degeneration which begins in the more excentric layers. This accompanies the atrophy of the reflected placenta. The second layer is an internal non-continuous fibrous layer, strewn with degenerated cellular elements and infiltrated with round cells. At the source of the reflection the internal layer of the cell is continued in its entirety unmodified in the zone of parietal fixation of the ovum, to form a complete capsule for the latter. The fibrinous layer has ceased, and the cuboidal epithelium which covers the sector of the free tube opposite the reflexa is arrested at the summit of the angle of reflexion or is reflected for a very short extent—1½ mm.—of the cellular layer of the reflexa. There is found at a distance from the sinus of reflexion some tracts which cover the external surface of the internal layer of the reflexa, where the fibrinous layer is non-adherent. Sixty-six days after the last menses, the reflexa presents neither vessels nor gasal buttress of vessels, and the living decidual cells become continuous with a parietal decidual layer, as in the uterus. The decidual action in the gravid tube during the first month is far from being as intense, as general, as it is in the gravid uterus at the same period.

116. **Uterine Displacements.**—While many uterine displacements cause no symptoms, they are, as a class, responsible for much suffering, and Frank discusses the subject in detail. The uterus is maintained at its proper level purely by its specific gravity and this implies an intact perineum. It lies in the position of anteversion and is movable within certain limits; its axis, with the bladder partially filled, is on a parallel with that of the inlet of the pelvis. The cervix is set in the vagina almost at a right angle. It is erroneous to suppose that the ligaments maintain the position of the uterus. They simply serve to prevent exaggerated mobility. They act just as guy ropes do upon a derrick, permitting it to swing backward and forward but always bringing it back to its proper place again. The causation of displacements is not a difficult thing to understand. They may be due to increase in weight or relaxation of the pelvic floor. Anterior displacements are rarely pathologic, when they are they do not offer a fruitful field for treatment. Medicinal treatment is of no value, except for relieving pain. Retrodisplacements are the ones which have been most treated, and Frank considers that there is no one method which applies to all. The mode of supporting treatment by pessaries has been used in maintaining the uterus in position until such a time as it could be restored to its normal size. No case can be cured by a pessary if there exists impairment of the pelvic floor or perineal laceration. It is contraindicated in inflammatory diseases of the appendages or tissues around the uterus. As to the operative treatment adopted for relieving the condition, he mentions those which are carried out most frequently, i. e., ventrofixation, ventrosuspension and the Alexander operation. As regards the first, it should not be attempted unless other means have been first faithfully tried. If the organ is fixed by the adhesion and it is necessary to open the abdomen to relieve these condi-

tions, then it may be considered. The operation of ventrosuspension, as advocated by Kelly, is somewhat better, but as its originator says, "It should be used only in cases of persistent retroflexion which refuses to yield to simpler plans of treatment through the vagina, and then only when it interferes seriously with the health." This last applies to all operative procedures. The other operative measure is the Alexander operation, and while it is condemned by many, it yields excellent results to some and is especially recommended by Kellogg. In every case attention should be given to the condition of the perineum, and this is especially true in those cases where prolapsus is the predominant symptom. Emmet claims that all cases of prolapse may be cured by plastic procedures by the way of the vagina. They certainly should be carried out in all cases where there is the least indication for them, otherwise neither ventrofixation, ventrosuspension nor pessaries of any sort will afford relief.

126. **Treatment of Inoperable Cancer.**—Coley's method of treatment with mixed toxins of erysipelas and bacillus prodigiosus is reported with additional cases. He has not changed his opinion as to the benefits of this method, but he finds the round-celled sarcoma much less susceptible than the spindle-celled, and the melanotic still less susceptible. The dose given depends largely on the vascularity of the tumor and the condition of the patient. The initial dose should seldom be more than one-half a minim diluted with boiled water, which should be gradually increased until reaction temperature reaches 102 or 103 F. After the dose has been increased to 1 minim, dilution is unnecessary, and if it is not injected directly into the tumor, much larger doses can be borne. He thinks the best preparation is mixed unfiltered toxins of erysipelas, but in weak individuals and children the filtered toxins are safer. He dwells on the importance of aseptic precautions and claims that the risk from the treatment, when properly given, is comparatively insignificant. If 10 per cent. instead of 1 per cent. of these otherwise hopeless patients can be cured, the outlook for this method is encouraging.

134. **Mechanism of Agglutination.**—The importance of the Widal reaction in clinical medicine has led Ernst and Robey to investigate its mechanism so far as it can be done. They review the various theories and observations on the subject by Gruber, Bordet, Pfaundler, Gengou, Rodet, Malvoz and others and give the results of their own tests. In conclusion they say that these studies do little more than furnish limited control of the work of others; but from these and other observations, it seems: 1, that the agglutinating property does not lie in, and is in no way connected with, the flagella of the bacteria concerned; 2, that agglutination is not to be accepted as a specific property connected with a condition of immunity, although this is a difficult idea to discard; 3, the homologous nature of agglutination can not be considered a positive characteristic, for how then could the clumping of typhoid bacilli by diphtheria antitoxin be explained; 4, finally, that no universally applicable explanation of agglutination has yet been offered. The most rational theory yet suggested seems to be that of Bordet, that an agglutinating agent—"agglutinine"—acts on an agglutinable substance—"substance agglutinée"—the nature of which is not yet determined—and that this reaction occurs not only with bacteria, but with many other elements—globules, casein, and precipitates of various kinds.

135. **Azoturia.**—The pathologic results of eleven cases of undoubted azoturia are described by Brinckerhoff. He concludes: 1. The acute degeneration of the liver and kidney, the proliferation of epithelioid cells in the lymph follicles of the spleen, and the focal necroses in the liver are similar to lesions found in man during various of the acute infectious diseases. In the human being such changes are generally regarded as manifestations of a toxemia. 2. The pigmentation of the spleen indicates nothing more than a destruction of blood-corpuscles, and is common to a number of diseases in both man and animals. 3. The degeneration of the psoas muscle is quite analogous to the Zenker's degeneration seen in typhoid fever. 4. The chronic interstitial nephritis indicates either that some toxic substance has acted for a considerable time, or that there have been previous acute attacks. We have, then, the picture of a pathologic process combining chronic and acute factors. This condition seems more reasonably explained by postulating the presence in the organism of a toxic substance, preferably one capable of causing both acute and chronic changes. In this study of the lesions found in azoturia, pathologic changes have been found which merit further study. Experiments on animals have been commenced, but the material at hand from that source is not sufficient to be reported at present, and is reserved for later publication.

136. **A Possible Cause of Azoturia.**—Balch, led by the similarity between certain of the symptoms in azoturia and those found in lead poisoning, has made examinations of urine in cases of azoturia, and found lead present in a large proportion of the cases, both of normal horses and those with azoturia. The results are suggestive, if not positive proof of this cause of the disorder.

137. **Sympathetic Ganglion Extract.**—Cleghorn's experiments point to the fact that the active depressor substance in sympathetic ganglion extract is not choline, but may be of similar nature to the substances described by Osborne and Vincent as present in extracts made from brain tissue. He makes no claims that the sympathetic ganglia possess an internal secretion.

142.—See abstract in The Journal of April 28, p. 1067.

143. **Improved Artificial Globe Implantation.**—The method devised by Suker consists in inserting, after enucleation of the eye, an artificial globe surrounded by an antiseptic surgeon's sponge, tied or sewed with catgut, which is inserted into the capsule cavity and sutured with chromicized catgut. The recti muscles are brought together in pairs and the whole fixed by an annular ligature. The black silk sutures are now removed from the recti muscles, and then the conjunctiva is brought over the muscles and sutured with silk or catgut. It is best to employ two sets of sutures for the conjunctiva; a so-called edge suture and an anchor suture alternating. This anchor or retention suture is placed as far back as possible from the cut edge of the conjunctiva in order to relieve any strain on the continuous or interrupted edge suture. It is best to apply four or five of these retention sutures, as this obviates any chance for gaping of the conjunctiva or tearing out of the edge sutures. They should be left in for two or three days after the removal of the edge sutures. The eye is now dressed with a dry-dressing gauze pad immersed in one part boric acid and four parts amyloform. Above all things, the use of pressure bandages should be avoided. It is advisable to employ an ice-bag for the first twenty-four to thirty-six hours; and great caution should be used to have everything thoroughly aseptic. An artificial shell—the ordinary or Snellen's—may be inserted at the expiration of a month or six weeks. If thought best, the nasal or temporal end of the conjunctiva may be left open and a fine gauze drainage inserted after operation, but ordinarily, this is not required. The advantages claimed for this operation are enumerated as follows: 1, less liability of extrusion of the globe; 2, almost absolute immobility of the inserted globe; 3, the range of movement of the stump thus obtained is just as great, if not greater, than by any other method; the inserted globe is more thoroughly protected from pressure of the shell than by the other operation on account of this so-called cushion; 5, the amount of shrinkage in consequence of the granulation tissue necessary to absorb the sponge is very trifling; 6, it takes but a trifle longer than a simple enucleation, due to the absorption process of the sponge; 7, no more reaction follows than after an ordinary enucleation.

148. **A Diagnostic Point in Third Nerve Paralysis.**—The point made by Wishart is that if the lesion is basal and unilateral there will be found paralysis of all the muscles supplied by the third nerve on the same side as the lesion, but if the lesion is nuclear and unilateral there will be a similar paralysis of all the muscles, except the inferior oblique, together with paralysis of the inferior oblique in the opposite eye. In the first instance, there is complete monocular third nerve paralysis, and in the second, complete unilateral nuclear

third-nerve paralysis. He discusses the anatomy of the conditions according to the best authorities in support of his view. The only case of the second variety of which he has any knowledge was one reported by him in 1897.

FOREIGN.

British Medical Journal, June 16.

Mauser Bullet Wounds and Amputation. William Stokes.—As the war advances, Stokes believes that we will have to modify the already conceived notions to some extent and consider bullet wounds as more formidable. From his experiences at Maritzburg Hospital and the general hospital, Mooi River, he finds them increasing in gravity in themselves and also more difficult to keep aseptic. The first is partly due to the Boer practice of splitting the ends of their bullets and making them expanding ones, and also to the closer range fighting of late. The difficulty of asepsis is probably due, not only to the thus increased severity of the wounds, but also to the greater hardships and their depressing effects, toward the close of the campaign. The cases he reports indicate, he thinks, that the Mauser bullet is not always so "harmless," "humane" or "merciful" a projectile as is supposed.

Recent Observation on Filaria Nocturna in Culex: Probable Mode of Infection in Man. George C. Low.—The author concludes from his observations and examinations, that the transmission of the filaria from mosquitoes to man is probably directly through its bite. He found that in filariated mosquitoes, the parasite takes up a position in the proboscis, the head invariably in advance and generally two of them together tête-a-tête.

The Lancet, June 9 and 16.

Massage in Recent Fractures and Other Common Injuries. William H. Bennett.—In this second lecture, the writer treats of the uses of massage in fractures of the patella and the olecranon. The two principal points dwelt on are: 1. The avoidance under all circumstances of any change of the upper part of the fractured patella or olecranon becoming adherent to the subjacent bone, and this can be insured by massage and lateral manipulation combined with gentle flexion and extension, during which the detached fragment is made to move as much as possible with the distal portion of the limb, the lateral movement being most easily managed and least disturbing. 2. All manipulations and passive movements must be preceded by smooth rubbing of the muscles. In this way the best results are obtained in these fractures, though this does not preclude the usual necessary operative treatment. Following this, he speaks of the effects of immediate massage and manipulation in dislocations. Here the chief difficulty is not the ruptured tendon but the muscular contraction. The capsule will heal equally well whether the joint is done up in splints or is manipulated. The torn capsule may be ignored and work against muscle waste by massage commenced immediately after reduction, using smooth rubbing for the first two days, after which passive motion should follow the massage. This passive movement should be free in all directions, save the direction of the muscles which tend to waste. Thus, in case of the shoulder, abduction of the arm from the trunk should not be practiced for a week or ten days after the injury, as the action of the adductors unopposed for the time by the weakened deltoid, tends to displace the head of the humerus inward. The cardinal point is to rectify muscular atrophy by massage and methodical exercises, with or without electricity and not to shorten the lax capsule. The treatment of sprains, wrenches, etc., is similarly taken up and practical points suggested. The effusion can be reduced by massage, and later, passive movements may be employed. The first of these should be of the simplest kind, and the last movement to be practiced should be that which was concerned in the production of the injury.

Contribution to Knowledge of Uric Acid Salts. F. W. Tunnicliffe and Otto Rosenheim.—From their experimental studies the authors conclude: 1. There is no evidence of the existence of a third order of uric acid salts, i. e., quadriurates, either in the artificial or the natural amorphous urinary deposits or in the fluids of the body. Under these circumstances it is regarded as advisable to discontinue the use of the term "quadriurate." 2. The substances obtained artificially under the conditions supposed to produce quadriurates consist of mixtures of uric acid and biurates pure or in varying proportions. 3. Natural amorphous urinary deposits consist of a mixture of uric acid with urates of sodium, ammonium, potassium, calcium, and magnesium—containing in most cases in addition phosphoric acid. 4. The property of some natural and artificial amorphous urates of showing the formation of uric-acid crystals under the influence of water is due to the dissolving out of the more soluble biurate moiety and a change in physical state of the remaining uric acid. 5. Any theory concerning the pathology or treatment of gout or the uric-acid diathesis built on the assumption of the existence of quadriurates requires reconsideration. 6. The existence of two forms—the tautomeric lactam and the lactim—may explain the variation in the physical and physiologic behavior of this acid and its salts.

Management of Anesthetic Where Respiratory Impediment Exists. Dudley W. Buxton.—The author reports three cases from which he lays down the following propositions as showing the need of caution in anesthesia and suggesting the remedies: 1. The individual patient possesses a certain respiratory power. Individuals differ greatly in this respect, and it is the business of the anesthetist to make himself acquainted with what may perhaps be termed the "personal respiratory equation of the patient." 2. This individual power of respiration is interfered with by every form of anesthetic, more by some than by others, but under any, the power of inspiration and expiration is lessened and in some cases to a very marked degree. 3. This lessened respiratory power may be of little or no consequence under normal conditions, but it becomes a factor of grave danger should any intercurrent cause of respiratory obstruction occur. For example, a delicate child breathing with difficulty through a blocked nasopharynx is placed under chloroform. The mouth is opened and the jaw is depressed while the tongue is forced back. The respiratory power would under these circumstances be wholly inadequate to overcome the increased difficulties of respiration. The child would die, and the death would be attributed to heart failure. The same occurs in cases of goiter, of malposition of the patient's body, of thoracic operation, etc. Thus it appears that all the cases cited fall into line and reveal to us not only the evident, but also the insidious, dangers associated with them.

Bulletin de l'Academie de Medecine (Paris), May 29

Human Hematolysin. Metchnikoff.—The research reported in this communication has been already cabled to the daily press as the discovery of a cure for leprosy. The subjects of the tests were lepers, as Carrasquilla in his serotherapy of leprosy inaugurated unwittingly these hemolytic experiments on man, and Metchnikoff utilized the results of this work as the first steps in the study of human hematolysis. His aim was to discover if it is possible to increase the resisting powers of the organism by stimulating blood-production. He had established that this could be accomplished in animals by minute, progressively increasing doses of a serum which in large doses destroyed the red corpuscles. Cautiously tested on four lepers, he found that hematopoiesis was increased as anticipated, without inconveniences or after-effects of any kind. Two other lepers were then treated, one with .5 c.c. of an extremely powerful hemolytic serum from a goat prepared with human blood, and the other with 5 c.c. of the same serum. After a brief preliminary period, in which the proportion of hemoglobin and red corpuscles fell below normal, they both increased to a marked extent in leper "A" for a few days and in leper "B" for three weeks, when a second injection was made without waiting for the subsidence of the effects of the first. Leper "A" was injected again in fifteen days with 3 c.c. of the same serum and leper "B" with 8 c.c. the second time. The effects were the same as at first: marked increase in hematopoiesis after a brief interval of decrease. The hemoglobin in leper "A" attained 120 to 125 per cent. The stimulating action of cellular toxins on the corresponding elements can thus be accepted as a general law. It establishes the possibility of augmenting the resistance of the tissues in case of need, but it by no means "cured the leprosy," and such an announcement is farthest from Metchnikoff's intentions.

Prophylaxis of Paludism.—The committee appointed for the study of malaria has drawn up a brief code of instructions for persons living or traveling in malarial countries. It states that a mixture of tar and petroleum is more satisfactory and durable than the latter alone, to pour on the surface of stagnant water to destroy the larvæ of the mosquito. The depth of the water need not be taken into account; 10 c.c. to the square meter is sufficient, applied early in the spring and renewed every fortnight. The larvæ are suffocated by obstruction of the air-passages with droplets of oil. Cisterns should be covered, or ordinary oil can be poured on the surface. Patients with malarial fever should be guarded with netting to prevent infection of mosquitoes.

Laparotomy for Retroversion of Gravid Uterus. PINARD.—In one case, the advanced pregnancy and in another an ovarian cyst rendered reduction impossible. The uterus was firmly lodged in retroversion. The laparotomy, performed by Mouchet, was successful in each case and pregnancy continued normally to term. The bladder and rectum should first be evacuated in such a case and every effort made to induce spontaneous reduction. If this fails, manual reduction through the vagina, with or without anesthesia, should be tried. A bulb inserted and inflated in the rectum is the only instrumental intervention permissible, unless laparotomy is indicated as a last resort.

Congenital Luxation of Hip-joint. DUCROCQUET.—The Paci-Lorenz method of bloodless reduction of congenital luxation of the hip-joint includes early use of the limb by the patient, but radiography has shown that although the functional results may be satisfactory, the anatomic conditions are sometimes far from normal. Docrocquet considers this a technical blunder and has treated eight patients by applying the principle of immobilization in an over-corrected position for a few months afterward, with the result that not only the functional but also the normal anatomic conditions are restored, as far as can be determined by radiography.

Bulletin de la Soc. Med. des Hop. de Paris, May 31 and June 6.

To Determine Size of Heart by Radiography. M. A. BÉCLÈRE.—There is one point in the radiograph or on the fluoroscope on which the rays fall perpendicularly. It is easy to determine this point and Béclère adjusts the tube until the perpendicular rays coincide with one edge of the heart. The tube is then moved in a parallel plane until perpendicular to the other edge; the distance between these two points, marked on the fluoroscope, is the exact diameter of the organ. He recommends placing the tube under the cot on which the subject reclines, or if he is seated, keeping the tube immovable and moving the patient and screen.

The Doubtful Ward at the Hopital des Enfants-Malades. MOIZARD.—More than 5000 children have passed through this ward in the last 4½ years, and only seven cases of contagion have been observed, six of measles, and one of diphtheria during the first month. The ward is divided by glass partitions and doors into twenty cells, each of which has a large window. The glass partitions do not quite reach the floor and are only 7½ ft. high, while the ceiling is more than twice this height. Each person entering the cell puts on one of several blouses kept constantly there and when he leaves dips his hands in a jar of a 1/1000 solution of mercury oxycyanid and, without wiping them, removes the blouse. The air circulates freely above and below, and yet aerial contagion has never occurred. Children with whooping-cough, with varicella and sometimes with other infectious diseases, are kept until recovery, as there is no place elsewhere for them in the hospital or on account of uncertain diagnoses. The glass walls of the cell prevent the children from feeling lonely in their isolation.

Echo Medical (Lille), June 3 and 10.

Conjugal Tabes. INGELRANS.—Babinski states that he has observed fifteen cases of conjugal tabes, and that there are thirteen on record in the literature. These experiences establish the existence of a special syphilis affecting predominantly the nervous system, irrespective of the soil. There must be, therefore, a variety of syphilis with a peculiar predilection for the nervous system, and persons deriving syphilis from this source are liable to have the nervous system affected. In the cases of "conjugal syphilis," in which both husband and wife may be assumed to have been infected from an identical source, if the syphilitic infection is of this essentially nerve-attacking variety, the manifestations will occur in the nervous system, but chance alone will determine whether they will appear as tabes, general paralysis or cerebral lesions.

Thermic Hyperesthesia in Neurasthenia. INGELRANS.—It has been established that hysteria may induce fever, and some writers claim that neurasthenia may produce the same phenomenon. Parisot and Ingelrans have been studying this "fever of neurasthenia" independently and have come to the same conclusion, proving that the rectal temperature remains normal or varies but a small fraction of a degree although the patients experience and appear to have fever. This phenomenon is due to a cutaneous vasodilatation which induces heat and is subjectively interpreted as fever by the abnormally acute perception of peripheral warmth peculiar to neurasthenic conditions.

"Head-stone" Extractors. H. GAUDIER.—The expression "he has a stone in his head" has been applied for centuries to mentally unbalanced persons. The charlatans of Europe used to profit by the opportunity the term afforded them, and claimed to be able to cure insanity, epilepsy, etc., by removing the stone which was causing the trouble by pressure on the brain. They incised the scalp and by a sleight-of-hand maneuver produced a blood-stained pebble which they exhibited to the by-standers and pocketed their fee of the grateful relatives. An interesting old picture has recently been found in an obscure corner of the museum at Saint-Omer, attributed to a Dutch painter who died in 1569. It portrays such a scene with several charlatans at work and additional patients being brought in.

Journal de Medecine de Paris, June 3 and 10.

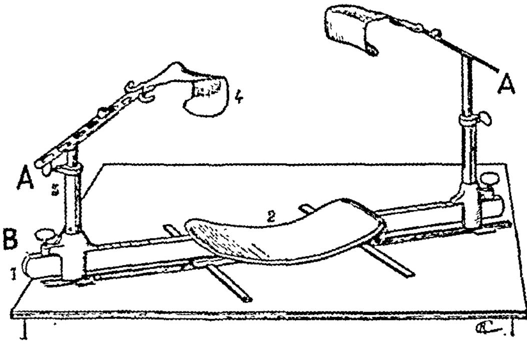
Iodin in Treatment of Tuberculosis. L. JOLLY.—"The increasing predisposition to infectious diseases in general and to tuberculosis in particular, is due to the insufficient phosphatic mineralization of our food on one hand, and on the other, to the alteration of the intercellular nutritional functions, from some toxic cause, which hinders cellular reconstitution and leads to the fabrication of additional toxic substances." Jolly asserts that the therapeutics of tuberculosis, as generally practiced, does not meet these conditions, which he accomplishes with large doses of metalloid iodin in an unstable organic combination associated with the physiologic phosphates, i. e., of potassium, sodium and iron. He has treated a hundred patients by this method, with the most gratifying results, and has kept all under observation for seven to nine years. He commences with 5 cg. of iodin a day and increases the amount by 5 cg. each week until a maximum of 40 cg. a day is reached. This treatment is continued for six months and then at half the dose for more than a year. No inconveniences have been experienced and all his patients in the second stage of the disease have been cured and kept in good health for eight years, and have no detectable signs of their former affection. He resumes the treatment at the slightest suspicion of relapse, and always during a "cold." He advises commencing treatment at the first indication of a progressive tendency to tuberculosis, which is usually a rebellious false anemia. It differs from true anemia in its appearance at any age; the number of the blood-corpuscles is not altered, but they become deformed, and the hemoglobin a reddish-yellow. The complexion is a yellowish- white, instead of the milky-white of true anemia. There is also more or less pronounced emaciation with loss of strength and appetite.

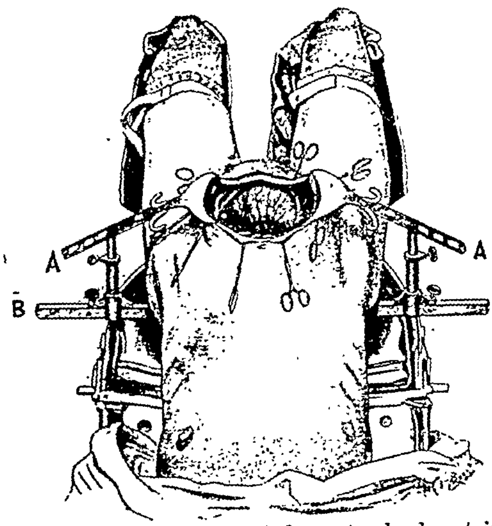
Medical Cure of Pulmonary Gangrene. DIAMANTBERGER.—The symptoms of pulmonary gangrene in a girl of 14 indicated an advanced stage of the lesion when first seen. An injection of 10 cg. of guaiacol in almond oil was made in the gluteal region every day, and a small rectal injection of twenty drops of the same solution was retained. The thorax over the cavity was painted with guaiacol and the rest of the body rubbed with camphorated alcohol. The symptoms rapidly improved to complete recovery. Ozenne has also reported a case of circumscribed pulmonary gangrene in a woman of 30, in which the patient recovered with no special treatment except injections of artificial serum.

Presse Medicale (Paris), May 30, June 2 and 6.

Pneumococcemia Resembling Plague. E. Tretrop.—A dock hand at Antwerp had his finger crushed, and from this portal of entry the pneumococcus invaded his system, inducing a typical bubo in the axilla and symptoms of general sepsis which suggested the plague. He was, therefore, inoculated with 40 c.c. of antiplague serum from Paris, but no cultures could be derived except of a virulent pneumococcus. The inoculation of serum, however, produced an unmistakably beneficial effect and convalescence commenced in two or three days afterward. There were no respiratory symptoms at any time.

Automatic Abdominal Retractor. T. Jonnesco.—Forceps with five long teeth on one blade and four on the other—nine-toothed forceps—are applied, three on each side of the abdominal incision, holding the edges of the peritoneum, subcutaneous tissue and skin, drawing the peritoneum far over, to prevent oozing of fluids into the wound. The two retractors, "A," "A," are broad and mounted on standards set in a cross-piece, "B," on which the patient lies, holding the entire apparatus firm although it is not fastened to the table in any way. When the forceps are in place, the retractors are hooked over the edges of the wound, which they enlarge and hold without the aid of an assistant, opening the field wide to the light. As the apparatus is fastened only to the patient himself, it yields and moves with him, and he can completely alter his position without affecting the grasp of the retractors. At the same time, there is not the slightest injurious compression, as the pressure comes solely on the dorso-lumbar-sacral region behind, and on the lips of the wound in front. Jonnesco has found this simple apparatus extremely useful and recommends it for all abdominal operations.





Lesions of the Cortical Nerve-Cells. G. Marinesco.—The lesions studied in Marinesco's latest research are what he calls "achromatosis," and a coagulating necrosis with disintegration of the coagulated portions or "corpuscular formation." He considers the latter a manifestation of serious disorders in nutrition owing to disturbances in the circulation. He observed it constantly in encephalitis, in experimental myelitis, in hyperthermia and occasionally after ligature of the abdominal aorta. Another lesion which resembles this is partial coagulation of the cytoplasm, without disintegration: a dark band extends from the wall of the nucleus into the principal prolongation. In certain affections he noted atrophy of the nerve-cell, which had shrunk to a fraction of its former width. In achromatosis of the giant cells of the pyramids, the protoplasm does not stain, but resembles ground-glass in its appearance; the nucleus is atrophied and homogeneous. He explains this by the abrupt dissolving of the chromatophile elements, loss of the affinities between the elementary granulations and their gradual disappearance by absorption or elimination. In normal conditions there is probably a dual current between the fluids in the nucleus and in the cytoplasm. When the normal balance between them is disturbed from any cause, if the fluid inside the nucleus is drawn out, the pressure from within is removed and the membrane of the nucleus retracts, leading to atrophy and "homogeneization" of the nucleus, and even of the nucleole. Any cause that tends to disturb the balance between the fluids in the cell is liable to induce this lesion, and it was found constantly, as anticipated, in acute and chronic inflammations of the brain and spinal cord, in slow obliterations of cerebral arterioles, etc. Another interesting fact noted by Marinesco was the phagocytic behavior of the cells of the neuroglia in most of these lesions of the nerve-cells, especially when the achromatic substance or the nucleus was affected. He believes that the nutritional balance between the different elements of the nervous system is maintained by the secretion of certain toxic substances produced by the nerve-cell, substances which prevent the excessive development of the neuroglia-cells and regulate the nutrition of the tissues. When the nerve-cell degenerates, these substances are no longer produced and consequently, the regulating function—which controlled the nutrition of the tissues—ceases to act. He maintains his former classification of primary and secondary lesions of the nerve-cells. Those described above are what he calls primary; the secondary lesions are due mostly to chromatolysis.

Significance of Persistent Chubbiness. L. Azoulay.—When a child or youth retains his chubbiness, especially of the face, at an age when other children or youths have lost theirs, it is an indication that the organism is correspondingly backward in its development, and should arouse apprehension in respect to the development of the sexual organs and the psychic faculties. Such young persons should not be forced in school or work, but should be kept in the country and every means taken to favor their physical development.

Early Diagnosis of Deafness with Paracoustic Test. P. Bonnier.—A person with normal hearing does not hear a tuning fork distinctly when it is placed on a remote part of the body, but a deaf person perceives the sound more distinctly than when the fork is vibrating on a level with his ear. It has been Bonnier's experience that a positive result with this paracoustic test invariably indicated an aural lesion entailing the prognosis of progressive deafness, sure to appear sooner or later, unless the lesion were cured without delay.

Semaine Medicale (Paris), May 30 and June 6.

Acid Intoxication in Diabetes. A. Jaquet.—We must not wait for onset of coma before we commence to neutralize the excess of acid in the blood in diabetes. Whenever the general appearance of the patient, or examination of the urine, indicates that coma is imminent, sodium bicarbonate should be administered in sufficient quantities—30 to 40 gm. a day. The proportion of ammonia in the urine affords a certain test by which to relax or accentuate the treatment. This alkaline treatment does not cure the disease, but it prolongs life and prevents accidents. Thirty-six observations are on record.

In 8 the alkaline was administered entirely or partially in the form of artificial serum—8½ liters in one case—with two successes. In the 28 other cases, the treatment was successful in 7; there was transient improvement in 7, and failure in 14. In a number of these cases the treatment was notoriously insufficient—what are a few grams of bicarbonate in comparison to the quantities of oxybutyric acid which Magnus-Levy has established? In others the alkaline was suspended after the subsidence of the most alarming symptoms, and resumed too late. The effect was most beneficial when administered at the commencement of the coma.

Centralbatt f. Chirurgie (Leipsic), June 9 and 16.

Chirol. New Method of Sterilizing Hands. R. Kossmann.—A Berlin firm has finally succeeded in producing a material composed of certain resins, oils, ether and alcohol, which when applied to the hands, dries in two or three minutes and forms a thin, strong, impermeable covering not interfering in the least with the sense of touch or the movements of the fingers. The entire field of operation can be easily sterilized in this way, also the hands of assistants and attendants. The varnish is not affected by water, solutions of sublimate or chinosol, nor even by 5 per cent. formalin, but washes off readily in alcohol. Kossmann mentions that after dipping three fingers in chirol he played a game of ten-pins and the coating showed no signs of wear until after he had rolled his twentieth heavy ball. It protects the operator against receiving as well as imparting infection, and "if midwives were compelled to use this inexpensive substance, a great boon would be conferred upon humanity."

Stereoscopic Views. H. Hildebrand.—The difficulty of taking stereoscopic radiographs has prevented the general use of this method, which is exceptionally valuable for the investigation of congenital luxations of the hip-joint. To facilitate its application Hildebrand has contrived a plate-holder to take two radiographs without disturbing the subject. The top is made of stout cardboard, but only the middle third is exposed; the rest is covered at each end with a sheet of zinc. cardboard. This part is then pushed along under the zinc, exposing the other half. The tube is also moved 7 cm. in a parallel plane. The two negatives thus obtained are photographed side by side at the proper distance—7 cm.—to adapt them to the size of an ordinary stereoscope. The views are amazingly accurate and life-like, enabling the conditions in the hip-joint to be determined with almost mathematical exactness.

Deutsche Medicinische Wochenschrift, May 31, June 6 and 13.

Permanent Canula for Carcinoma of Esophagus. C. A. Ewald.—The points of special interest in this case-report are the benefits of fastening the permanent sound by drawing the strings through the nostrils and tying them across the septum of the nose, instead of to the ears. Another point is the possibility that the stenosis may become impermeable for a sound, owing to the winding course of the passage, long before the ability to swallow fluids is lost.

Hysteric Deafness. E. Barth.—Notwithstanding absolute bilateral deafness, unconscious musical tone-perception may be retained, as in the following observation: The child always followed the key set by the piano and also the tempo, if gradually changed, but was unable to consciously hear a sound. Her deafness was the result of a fright, and disappeared suddenly during the night after a few weeks. Barth concludes that there must be an acoustic center, "below the threshold of the consciousness."

Loss of Brain Substance Without Functional Disturbances. A. Gutmann.—A lad of 12 was caught between two ox-carts and his right temporal region crushed with the loss of three fragments of brain matter the size of a lentil seed and another the size of a walnut. He recovered without a trace of functional disturbance.

Relapses. Lippmann.—After recovery from an infectious disease some of the germs may still linger in the organism, encapsulated in an inflammatory reactive process, where they may remain harmlessly imprisoned for years or become liberated by a trauma affecting the region, by some violent emotion or exposure to cold. In the latter cases the blood, driven inward from the periphery by the emotion or cold, would scarcely have power to break the wall of the capsule, but when the reaction follows and the blood surges back to the periphery, it leaves a vacuum in which the wall of the encapsulated focus may succumb to the negative pressure. He describes some typical instances of relapses after infectious diseases, in which this mechanism was clearly evident, among them a case of erysipelas recurring after every fit of anger, and another of scarlet fever in which a ganglionary enlargement in the neck persisted for several weeks after recovery. It was then treated with hot cataplasms, resulting in its complete subsidence in twenty-four hours, with the simultaneous return of the scarlet fever, eruption and temperature. In another instance an abscess developed from a latent focus of osteomyelitis after trauma, although thirty years had elapsed since the last perceptible manifestation of the morbid process.

Benefits of Hot Baths in Climacteric Disturbances. Gottschalk.—Sweats and "hot flashes" consecutive to removal of the uterus and adnexæ, were uninfluenced by organotherapy in the two observations described but they promptly subsided after a few hot baths of twenty minutes each, with 5 pounds "Stassfurt salts" dissolved in the water, taken just before retiring. In a number of cases in the writer's experience a month of these baths completely cured all the climacteric disturbances. He ascribes the benefit to the dilatation of the peripheral vessels which they induce. This relieves the arterial pressure, probably excessive on account of the absence of the menstrual flux.

Dangers of Lumbar Puncture. F. Gumprecht.—Fifteen instances have been reported in which death followed lumbar puncture, and although it was a mere coincidence in a few cases, yet in large proportion, an evident connection between the intervention and the fatal termination could not be excluded Gumprecht adds two new observations to the list, and on reviewing these and the rest on record, he finds that the fatal cases were almost invariably persons with tumors of the brain, and especially in the posterior fossa. Even before the puncture the patient showed symptoms of cerebral pressure, and the pain in the head increased to such an unbearable degree that the attempt was abandoned in several instances. The pressure of the cerebrospinal fluid was not always excessive: occasionally it fell to zero after 5 c.c. had been withdrawn but usually about 50 c.c. escaped under high pressure. In most of the fatal cases death followed the puncture within a few minutes; when delayed, the headache continued, with loss of consciousness and sopor for several hours, then abrupt cyanosis and cessation of respiration, although the heart continued to beat for nearly an hour with artificial respiration. Certain experiences seem to indicate the possibility that trephining and puncture of the ventricle might supplement artificial respiration and save the patient. The primary paralysis of respiration may be due to disturbance of the hydrostatic balance with consequent injury of the respiration center or its conducting fibers. The heart action subsides very gradually. In the cadaver, the cavities of the central nervous system toward the brain from the tumor were found enlarged, while toward the spinal cord they were smaller than usual. The point of obstruction between the cerebral and spinal lymph was either at the aqueduct—due to the direct pressure of the tumor—or at the foramen of Majendie, from a plug of cerebellum having been forced into the opening.

Muenchener Medicinische Wochenschrift, June 5 and 12.

Changes in Urine After Palpation of Kidney. C. Menge.—In fourteen out of twenty-one cases of nephroptosis, investigation with palpation of the kidney caused the appearance of slight, transient albuminuria and hematuria, leading to erroneous deductions in respect to the prognosis until it was noticed that the urine had returned to normal when examined the next day and afterward. In Menge's experience nephroptosis and chronic anemia are frequently associated in [illegible] girls and mutiparæ. This suggests a connection between th anemia and the slight albuminuria and hematuria, which possibly induced by the pressure of tight clothing on an abnormally exposed kidney, the same as by palpation. Cyclic intermittent albuminuria are most frequent at the age of rapid growth, especially in poorly nourished individuals. The albuminuria usually appears on rising after prolonged rest in bed, i. e., when the kidney descends and the pressure of the clothing is again experienced. All these morbid conditions are best influenced by protecting the kidneys against pressure from without. Massage of the kidneys and trusses with kidney pads should be avoided in nephroptosis.

Hemoglobinuria in Splenomegalic Icterus. BETTMANN.—The symptoms in the observation reported corresponded to Hayem's "chronic, infectious splenomegalic icterus," but there was also occasional, intermittent hematuria. The affection had commenced in childhood; the icterus was pronounced and chronic, the liver apparently normal on auscultation and palpation, but the spleen measured 16 by 27 cm. The exacerbations of the icterus were always consecutive to excesses in eating or drinking, emotions, physical exertion, such as marching or dancing, or to cold. This sequence suggested paroxysmal hemoglobinuria and hemoglobinemia as important factors in the etiology of the affetion. The primary cause is possibly a congenital idiosyncrasy of the blood, allowing the more or less continuous passage of small amounts of hemoglobin into the serum. They are disposed of in the organism and do not pass into the urine except under certain rare circumstances. This hypothesis explains the exacerbations of the icterus and the hypertrophy of the spleen, which is evidently enlargement from deposits of the waste of the red corpuscles. No bile pigment was detected in the urine during the entire year of observation and the patient was subjectively well except during exacerbations, which were usually inaugurated with a chill and pains in the trunk and extremities. [Gilbert and Fournier have recently described a somewhat similar case of what they call hypersplenomegalic biliary cirrhosis, characterized by chronic icterus, enormously hypertrophied spleen and comparatively slight enlargement of the liver. They attribute the etiology to an ascending, infectious angiocholitis, primarily a biliary affection due to invasion of the intrahepatic passages by intestinal micro-organisms. The spleen may increase to a length of 30 cm. Hepatic colic was the first manifestation. See THE JOURNAL, xxxiv, 1675.—ED.]

Calcium Carbid in Carcinoma of Uterus. W. GRUSDEW.—Scarcely a day passes that a patient with inoperable carcinoma of the uterus is not brought to Grusdew's clinic. The more extensive his experience, the higher is his appreciation of calcium carbid as a palliative measure in these cases. He places one or two pieces of the carbid, the size of a hazel-nut, on the neoplasm and packs the vagina with gauze tampons over a cotton wad, protecting the vaginal walls from the chemical action, which consists in the generation of acetylene, etc. The vagina is not packed so tightly as to interfere with micturition or escape of the gas. The patient is then dismissed. In one to three days the vagina is rinsed out, and the application is renewed, whenever hemorrhage or fetid discharges render it necessary. One application transforms the surface of the neoplasm into a clean wound which bleeds very little if at all. The secretion is diminished and rendered odorless and there is no danger connected with the treatment if ordinary precautions are observed. Grusdew recommends it as a preliminary measure to cleanse the surface of the carcinoma before cauterizing, and he has found it extremely beneficial in curing erosions and benign ulcerations of the vaginal portion of the uterus In the latter case it is applied in the form of powder.

The Public Service.

ARMY CHANGES.

Movements of Army Medical Officers under orders from the Adjutant General's Office. Washington, D. C., June 7 to 21, 1900. inclusive:

William Alden, acting asst.-surgeon, from Lynn, Mass., to duty in the Department of California.

Bailey K. Ashford, lieutenant and asst.-surgeon. U. S. Army, from Washington Barracks, D. C., to duty at Fort Slocum, N. Y.

Lewis Balch, major and surgeon, Vols., honorably discharged the [illegible], to take effect July 15, 1900.

Edmund Barry, acting asst.-surgeon, from Fort Wadsworth to Fort Slocum, N. Y., to accompany recruits to San Francisco, Cal., and return to his proper station.

Robert M. Blanchard, acting asst.-surgeon, from Batavia, Ohio, to duty in the Department of California.

Madison H. Bowman, asting asst.-surgeon, from Toledo, Ohio, to duty in the Department of California.

Louis Brechemin, major and surgeon, U. S. A., sick-leave extended.

Charles E. Bruuhl, acting asst.-surgeon, from Waco, Texas, to Tampa, Fla., and thence to Havana, Cuba, for assignment.

Edward C. Carter, major and surgeon, U. S. A., member of an examining board at Washington, D. C.

Robert P. Cooke, acting asst.-surgeon, from Boyce, Va., to Tampa, Fla., and thence to Havana, Cuba, for assignment.

Orlando Ducker, major and surgeon, Vols., leave of absence granted: relieved from further duty in the Division of Cuba, and on expiration of his leave of absence to report at San Francisco, for duty in the department of California.

Arthur M. Fraser, acting asst.-surgeon, from Washington, D. C., to New York City, to join the transport *Crook*

Leigh A. Fuller, lieutenant and asst.-surgeon, U. S. A., from Fort Monroe, Va., to report to the commanding general, Deparment of California, for further orders.

Edward F. Gettings, acting asst.-surgeon, from duty at Fort Hood, N. Y., to proceed by the first available transport to Santiago, Cuba.

Frederick F. Jenkins, acting asst.-surgeon, from Carbondale, Pa., to duty in the Department of California.

Frank R. Keefer, major and surgeon, Vols., having tendered his resignation, is honorably discharged from the volunteer service, to take effect June 15, 1900. As captain and asst.-surgeon, U. S. A., leave of absence is granted, on the expiration of which he is required to report for duty at Fort Monroe, Va.

James C. Merrill, major and surgeon, U. S. A., member of an examining board at Washington, D. C.

Albert Moser, acting asst.-surgeon, from Lima, Ohio, to the Department of California.

Edward L. Munson, captain and asst.-surgeon, U. S. A., member of an examining board at Washington, D. C.

Eduardo C. Poey, acting asst.-surgeon, from temporary duty at Fort Riley, Kans., to accompany a detachment of the 6th U. S. Cavalry to Manila, P. I., and on arrival to report for duty in the Division of the Philippines.

William W. Quinton, captain and asst.-surgeon, U. S. A., from New York City, to duty at Fort Ethan Allen, Vt.

Charles J. Rowan, acting asst.-surgeon, from Chicago, Ill., to the Department of California.

Louis S. Tesson, major and surgeon, U. S. A., from Fort Ethan Allen, Vt., to duty at Vancouver Barracks, Wash.

Harry H. Van Kirk, acting asst.-surgeon, from Sunbury, Ohio, to the Department of California.

Samuel M. Waterhouse, lieutenant and asst.-surgeon, U. S. A., leave of absence granted.

NAVY CHANGES.

Changes in the Medical Corps of the U. S. Navy for the week ending June 23, 1900.

P. A. Surgeon A. R. Alfred, detached from the *Texas* and ordered to the Asiatic Station, via the *Nippon Maru* sailing from San Francisco, Cal., July 10.

P. A. Surgeon G. A. Lung, order of May 25, modified; ordered to the Cavite naval station.

The following are commissioned assistant-surgeons, to take rank from June 7, 1900, in the order named: J. J. Snyder, H. A. Dunn, A. Stuart, E. M. Blackwell, W. H. Ulsh, M. V. Stone, C. R. Burr, G. F. Freeman, R. O. Marcour, J. K. Payne, Jr., J. Stepp, C. H. DeLancy, F. M. Bogan, R. K. McClanahan, W. E. G. High.

MARINE-HOSPITAL CHANGES.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the U. S. Marine-Hospital Service for the 7 days ending June 21, 1900.

Surgeon H. R. Carter, detailed as chief quarantine officer of the Island of Cuba.

Surgeon A. H. Glennan, relieved from duty at New Orleans, La., and directed to proceed to Havana, Cuba, via Washington, D. C., and New York City, and report to Surgeon H. R. Carter for duty.

Surgeon Eugene Wasdin, granted leave of absence for 10 days from June 21.

Surgeon G. M. Magruder, upon being relieved from duty at London, England, to proceed to Memphis, Tenn., and assume command of the service.

P. A. Surgeon A. C. Smith, relieved from duty at Hamburg, Germany, and directed to proceed to New York City, and report by wire for orders.

P. A. Surgeon Rupert Blue, relieved from duty at Genoa, Italy, and directed to proceed to New York City, and report by wire for orders.

P. A. Surgeon J. H. Oakley, relieved from duty at Queenstown (Cork), Ireland, and directed to proceed to Evansville, Ind., and assume command of the service.

P. A. Surgeon E. K. Sprague, relieved from duty at Antwerp, Belgium, and directed to proceed to Detroit, Mich., and report to medical officer in command for duty and assignment to quarters.

P. A. Surgeon A. R. Thomas, relieved from duty at Rotterdam, Netherlands, and directed to proceed to London, England, and de-

The pressure of the cerebrospinal fluid was not always excessive: occasionally it fell to zero after 5 c.c. had been withdrawn but usually about 50 c.c. escaped under high pressure. In most of the fatal cases death followed the puncture within a few minutes; when delayed, the headache continued, with loss of consciousness and sopor for several hours, then abrupt cyanosis and cessation of respiration, although the heart continued to beat for nearly an hour with artificial respiration. Certain experiences seem to indicate the possibility that trephining and puncture of the ventricle might supplement artificial respiration and save the patient. The primary paralysis of respiration may be due to disturbance of the hydrostatic balance with consequent injury of the respiration center or its conducting fibers. The heart action subsides very gradually. In the cadaver, the cavities of the central nervous system toward the brain from the tumor were found enlarged, while toward the spinal cord they were smaller than usual. The point of obstruction between the cerebral and spinal lymph was either at the aqueduct—due to the direct pressure of the tumor—or at the foramen of Majendie, from a plug of cerebellum having been forced into the opening.

Muenchener Medicinische Wochenschrift, June 5 and 12.

Changes in Urine After Palpation of Kidney. C. Menge.—In fourteen out of twenty-one cases of nephroptosis, investigation with palpation of the kidney caused the appearance of slight, transient albuminuria and hematuria, leading to erroneous deductions in respect to the prognosis until it was noticed that the urine had returned to normal when examined the next day and afterward. In Menge's experience nephroptosis and chronic anemia are frequently associated in young girls and nulliparæ. This suggests a connection between the anemia and the slight albuminuria and hematuria, which is possibly induced by the pressure of tight clothing on an abnormally exposed kidney, the same as by palpation. Cyclic and intermittent albuminuria are most frequent at the age of rapid growth, especially in poorly nourished individuals. The albuminuria usually appears on rising after prolonged rest in bed, i. e., when the kidney descends and the pressure of the clothing is again experienced. All these morbid conditions are best influenced by protecting the kidneys against pressure from without. Massage of the kidneys and trusses with kidney pads should be avoided in nephroptosis.

Hemoglobinuria in Splenomegalic Icterus. BETTMANN.—The symptoms in the observation reported corresponded to Hayem's "chronic, infectious splenomegalic icterus," but there was also occasional, intermittent hematuria. The affection had commenced in childhood; the icterus was pronounced and chronic, the liver apparently normal on auscultation and palpation, but the spleen measured 16 by 27 cm. The exacerbations of the icterus were always consecutive to excesses in eating or drinking, emotions, physical exertion, such as marching or dancing, or to cold. This sequence suggested paroxysmal hemoglobinuria and hemoglobinemia as important factors in the etiology of the affction. The primary cause is possibly a congenital idiosyncrasy of the blood, allowing the more or less continuous passage of small amounts of hemoglobin into the serum. They are disposed of in the organism and do not pass into the urine except under certain rare circumstances. This hypothesis explains the exacerbations of the icterus and the hypertrophy of the spleen, which is evidently enlargement from deposits of the waste of the red corpuscles. No bile pigment was detected in the urine during the entire year of observation and the patient was subjectively well except during exacerbations, which were usually inaugurated with a chill and pains in the trunk and extremities. [Gilbert and Fournier have recently described a somewhat similar case of what they call hypersplenomegalic biliary cirrhosis, characterized by chronic icterus, enormously hypertrophied spleen and comparatively slight enlargement of the liver. They attribute the etiology to an ascending, infectious angiocholitis, primarily a biliary affection due to invasion of the intrahepatic passages by intestinal micro-organisms. The spleen may increase to a length of 30 cm. Hepatic colic was the first manifestation. See THE JOURNAL, xxxiv, 1675.—ED.]

Calcium Carbid in Carcinoma of Uterus. W. GRUSDEW.—Scarcely a day passes that a patient with inoperable carcinoma of the uterus is not brought to Grusdew's clinic. The more extensive his experience, the higher is his appreciation of calcium carbid as a palliative measure in these cases. He places one or two pieces of the carbid, the size of a hazel-nut, on the neoplasm and packs the vagina with gauze tampons over a cotton wad, protecting the vaginal walls from the chemical action, which consists in the generation of acetylene, etc. The vagina is not packed so tightly as to interfere with micturition or escape of the gas. The patient is then dismissed. In one to three days the vagina is rinsed out, and the application is renewed, whenever hemorrhage or fetid discharges render it necessary. One application transforms the surface of the neoplasm into a clean wound which bleeds very little if at all. The secretion is diminished and rendered odorless and there is no danger connected with the treatment if ordinary precautions are observed. Grusdew recommends it as a preliminary measure to cleanse the surface of the carcinoma before cauterizing, and he has found it extremely beneficial in curing erosions and benign ulcerations of the vaginal portion of the uterus In the latter case it is applied in the form of powder.

The Public Service.

ARMY CHANGES.

Movements of Army Medical Officers under orders from the Adjutant General's Office, Washington, D. C., June 7 to 21, 1900, inclusive:

William Alden, acting asst.-surgeon, from Lynn, Mass., to duty in the Department of California.

Bailey K. Ashford, lieutenant and asst.-surgeon, U. S. Army, from Washington Barracks, D. C., to duty at Fort Slocum, N. Y.

Lewis Balch, major and surgeon, Vols., honorably discharged from the service, to take effect July 15, 1900.

Edmund Barry, acting asst.-surgeon, from Fort Wadsworth to Fort Slocum, N. Y., to accompany recruits to San Francisco, Cal., and return to his proper station.

Robert M. Blanchard, acting asst.-surgeon, from Batavia, Ohio, to duty in the Department of California.

Madison H. Bowman, asting asst.-surgeon, from Toledo, Ohio, to duty in the Department of California.

Louis Brechemin, major and surgeon, U. S. A., sick-leave extended.

Charles E. Bruuhl, acting asst.-surgeon, from Waco, Texas, to Tampa, Fla., and thence to Havana, Cuba, for assignment.

Edward C. Carter, major and surgeon, U. S. A., member of an examining board at Washington, D. C.

Robert P. Cooke, acting asst.-surgeon, from Boyce, Va., to Tampa, Fla., and thence to Havana, Cuba, for assignment.

Orlando Ducker, major and surgeon, Vols., leave of absence granted: relieved from further duty in the Division of Cuba, and on expiration of his leave of absence to report at San Francisco, for duty in the department of California.

Arthur M. Fraser, acting asst.-surgeon, from Washington, D. C., to New York City, to join the transport *Crook*

Leigh A. Fuller, lieutenant and asst.-surgeon, U. S. A., from Fort Monroe, Va., to report to the commanding general, Deparment of California, for further orders.

Edward F. Gettings, acting asst.-surgeon, from duty at Fort Hood, N. Y., to proceed by the first available transport to Santiago, Cuba.

Frederick F. Jenkins, acting asst.-surgeon, from Carbondale, Pa., to duty in the Department of California.

Frank R. Keefer, major and surgeon, Vols., having tendered his resignation, is honorably discharged from the volunteer service, to take effect June 15, 1900. As captain and asst.-surgeon, U. S. A., leave of absence is granted, on the expiration of which he is required to report for duty at Fort Monroe, Va.

James C. Merrill, major and surgeon, U. S. A., member of an examining board at Washington, D. C.

Albert Moser, acting asst.-surgeon, from Lima, Ohio, to the Department of California.

Edward L. Munson, captain and asst.-surgeon, U. S. A., member of an examining board at Washington, D. C.

Eduardo C. Poey, acting asst.-surgeon, from temporary duty at Fort Riley, Kans., to accompany a detachment of the 6th U. S. Cavalry to Manila, P. I., and on arrival to report for duty in the Division of the Philippines.

William W. Quinton, captain and asst.-surgeon, U. S. A., from New York City, to duty at Fort Ethan Allen, Vt.

Charles J. Rowan, acting asst.-surgeon, from Chicago, Ill., to the Department of California.

Louis S. Tesson, major and surgeon, U. S. A., from Fort Ethan Allen, Vt., to duty at Vancouver Barracks, Wash.

Harry H. Van Kirk, acting asst.-surgeon, from Sunbury, Ohio, to the Department of California.

Samuel M. Waterhouse, lieutenant and asst.-surgeon, U. S. A., leave of absence granted.

NAVY CHANGES.

Changes in the Medical Corps of the U. S. Navy for the week ending June 23, 1900.

P. A. Surgeon A. R. Alfred, detached from the *Texas* and ordered to the Asiatic Station, via the *Nippon Maru* sailing from San Francisco, Cal., July 10.

P. A. Surgeon G. A. Lung, order of May 25, modified; ordered to the Cavite naval station.

The following are commissioned assistant-surgeons, to take rank from June 7, 1900, in the order named: J. J. Snyder, H. A. Dunn, A. Stuart, E. M. Blackwell, W. H. Ulsh, M. V. Stone, C. R. Burr, G. F. Freeman, R. O. Marcour, J. K. Payne, Jr., J. Stepp, C. H. DeLancy, F. M. Bogan, R. K. McClanahan, W. E. G. High.

MARINE-HOSPITAL CHANGES.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the U. S. Marine-Hospital Service for the 7 days ending June 21, 1900.

Surgeon H. R. Carter, detailed as chief quarantine officer of the Island of Cuba.

Surgeon A. H. Glennan, relieved from duty at New Orleans, La., and directed to proceed to Havana, Cuba, via Washington, D. C., and New York City, and report to Surgeon H. R. Carter for duty.

Surgeon Eugene Wasdin, granted leave of absence for 10 days from June 21.

Surgeon G. M. Magruder, upon being relieved from duty at London, England, to proceed to Memphis, Tenn., and assume command of the service.

P. A. Surgeon A. C. Smith, relieved from duty at Hamburg, Germany, and directed to proceed to New York City, and report by wire for orders.

P. A. Surgeon Rupert Blue, relieved from duty at Genoa, Italy, and directed to proceed to New York City, and report by wire for orders.

P. A. Surgeon J. H. Oakley, relieved from duty at Queenstown (Cork), Ireland, and directed to [illegible] ceed to E[illegible] e, Ind., and assume command of the serv[illegible]

P. A. Surgeon E. K. [illegible] ieved [illegible] at A[illegible]
Belgium, and directed [illegible]
medical officer in com[illegible]

P. A. Surgeon A. R. [illegible] ed f[illegible] ott[illegible]
Netherlands, and di[illegible] to L[illegible] an

tailed for duty in the office of the U. S. Consul-General at that place.

P. A. Surgeon H. W. Vickes, relieved from duty at Glasgow, Scotland, and directed to proceed to Cincinnati, Ohio, and assume command of the service.

P. A. Surgeon J. B. Greene, relieved from duty at Bremen, Germany, and detailed for duty in the office of the U. S. Consul-General at Berlin, Germany.

Asst.-Surgeon H. S. Grubbs, relieved from duty at Havre, France, and detailed for duty in the office of the U. S. Consul-General at Paris, France.

Asst.-Surgeon H. B. Parker, upon being relieved from duty at Santiago, Cuba, to proceed to New Orleans, La., and report to medical officer in command for duty and assignment to quarters.

Asst.-Surgeon R. H. Von Ezdorf, relieved from duty at Savannah, Ga., and detailed as quarantine officer at the port of Santiago, Cuba, proceeding to station via Washington, D. C. and New York City.

Asst.-Surgeon J. F. Anderson, relieved from duty at Marseilles, France, and detailed for duty in the office of the U. S. Consul-General at Vienna, Austria.

Asst.-Surgeon W. C. Hobdy, relieved from duty at Southampton, England, and directed to proceed to New York City, and report by wire for orders.

Asst.-Surgeon J. W. Schereschewsky, directed to assume temporary command of the service at New Orleans, La.

Acting Asst.-Surgeon W. H. Marsh, granted leave of absence for 18 days from June 5.

Acting Asst.-Surgeon W. C. Mason, granted leave of absence for 5 days from June 24.

Hospital Steward W. F. Schlaar, relieved f rom duty at the port of Washington, D. C., and directed to report to Surgeon L. L. Williams, Immigration Depot, New York City for duty.

HEALTH REPORTS.

The following cases of smallpox, yellow fever, cholera, and plague have been reported to the Surgeon General, Marine-Hospital Service, during the week ended June 23, 1900:

SMALLPOX—UNITED STATES

District of Columbia: Washington, June 9-16, 8 cases.

Illinois: Cairo, June 2-9, 1 case.

Indiana: Evansville, June 8-16, 2 cases.

Iowa: Ottumwa, April 28 to May 5, 1 case.

Kentucky: Covington, June 8-16, 9 cases.

Louisiana: New Orleans, June 8-16, 35 cases, 6 deaths; Shreveport, June 2-9, 5 cases.

Massachusetts: Fall River, June 8-16, 3 cases; Lowell, June 8-16, 3 cases.

Michigan: Grand Rapids, June 8-16, 2 cases.

Minnesota: Minneapolis, May 26 to June 9, 26 cases, 1 death.

New Hampshire: Manchester, June 8-16, 9 cases.

Ohio: Cleveland, June 8-16, 28 cases, 2 deaths; Youngstown, June 8-16, 1 case.

Pennsylvania: Pittsburg, June 8-16, 2 cases.

Porto Rico: Ponce, May 27 to June 4, 1 case.

South Carolina: Greenville, June 8-16, 2 cases.

Utah: Ogden, May 1-31, 3 cases; Salt Lake City, June 8-16, 5 cases.

Washington: Spokane, June 8-16, 1 case.

West Virginia: Charlestown, June12, 10 cases.

SMALLPOX—FOREIGN.

Austria: Prague, May 28 to June 2, 11 cases.

Belgium: Antwerp, May 19-26, 1 case, 3 deaths.

Brazil: Rio de Janeiro, April 13 to May 11, 18 deaths.

Canada: Montreal, June 4, 30 cases.

England: Liverpool, May 26 to June 2, 2 cases; London, May 26 to June 2, 7 cases.

France: Nice, May 26 to June 6, 3 cases; Paris, May 26 to June 2, 1 death.

Germany: Stettin, May 19-26,1 case.

Gibraltar: May 20-29, 4 cases.

Greece: Athens, May 19-26, 4 cases, 2 deaths.

India: Bombay, May 8-13, 24 deaths; Kurrachee, May 6-13, 11 cases, 9 deaths; Madras, May 5-11, 1 death.

Mexico: Chihuahua, June 2-9, 2 deaths; Vera Cruz, June 2-9, 2 deaths.

Philippines: Manila, April 28 to May 5, 2 cases.

Russia: Moscow, May 19-26, 9 cases, 4 deaths; Odessa, May 26 to June 2, 11 cases, 1 death; St. Petersburg, May 19-26, 33 cases, 12 deaths; Warsaw, May 12-19, 2 deaths.

Spain: Corunna, May 26 to June 2, 1 death; Madrid, May 5-19, 21 deaths.

Straits Settlements: Singapore, April 26 to May 5, 5 deaths.

Uruguay: Montivideo, April 21 to May 5, 2 cases.

YELLOW FEVER.

Brazil: Rio de Janeiro, April 13 to May 11, 46 deaths.

Colombia: Barranquilla, May 26 to June 2, 5 cases, 3 deaths.

Cuba: Havana, June 2-9, 2 deaths.

Mexico: Laguna, 16, present; Vera Cruz, June 2-9, 17 cases, 10 deaths.

CHOLERA.

India: Bombay, May 8-15, 15 deaths; Kurrachee, May 6-13; 2 cases; Madras, May 5-11, 1 death.

PLAGUE.

India: Bombay, May 8-15, 304 deaths; Kurrachee, May 6-13, 178 cases, 184 deaths.

Japan: Osaka, May 13-25, 6 cases; Shidzuoka, May 14-17, 3 cases.

Philippines: Manila, April 28 to May 5, 9 cases, 7 deaths.

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

is published weekly, at 61 Market Street, Chicago, Ill. The subscription price is five dollars per annum in advance. Postage in the United States, Canada, Mexico, Guam, Porto Rico, and the Philippines, free; foreign postage, $2.50. Subscriptions may commence at any time. Volumes begin with the first issue of January and of July.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

The qualifications for membership require that the applicant be a member, in good standing, of a state or local medical society entitled to send delegates to the annual meeting of the American Medical Association. A list of these societies will be sent on request. Applications must be accompanied with a certificate showing that the applicant is a member of a recognized society, and should be sent with the annual dues—five dollars—to the treasurer, Dr. Henry P. Newman, 100 Washington Street, Chicago. Members receive the Journal free. Subscribers to the Journal may become members of the Association without expense if they are members of medical societies recognized by the Association, and those desiring to have their names transferred from the subscription to the membership lists should send certificates as above, with a receipt for their subscription to the Journal, covering the current fiscal year.

FISCAL YEAR.

The fiscal year of the American Medical Association is from January 1 to December 31; and the annual dues paid by a new member cover only the fiscal year, no matter at what time of year the membership is obtained. Those who pay their dues and join the Association at the annual meeting in June, for instance, pay only for the fiscal year which ends with the December following, and the annual dues for the following fiscal year are payable the succeeding January, at which time the treasurer sends a statement to each member. Such members, however, are entitled to the Journal for the full year, even though the membership be not continued.

PAPERS READ AT THE ANNUAL MEETING.

"Every paper received by this Association and ordered to be published, and all plates or other means of illustration, shall be considered the exclusive property of the Association. . . . The Board of Trustees shall have full discretionary power to omit from the published transactions, in part or in whole, any paper that may be referred to it by the Association or either of the Sections, unless specially instructed to the contrary by vote of the Association." (From Article V of the By-laws.)

NEWS.

Our readers are requested to send us items of news of a medical nature, also marked copies of local newspapers containing matters of interest to members of the medical profession. We shall be glad to know the name of the sender in every instance.

ORIGINAL PAPERS.

Articles are accepted for publication with the understanding that they are contributed solely to this journal, unless a definite understanding be had to the contrary.

COPYRIGHT.

Matter appearing in The Journal of the American Medical Association is covered by copyright, but, as a general thing, no objection will be made to the reproduction of anything appearing in its columns if proper credit be given.

CONTRIBUTIONS TYPEWRITTEN.

It will be satisfactory to all concerned if authors will have their contributions typewritten before submitting them for publication. The expense is small to the author—the satisfaction is great to the editor and printer. We can not promise to return unused manuscript.

Half-tones, zinc etchings and other illustrations will be furnished by the Journal when photographs or drawings are supplied by the author.

ADVERTISEMENTS.

Advertising forms go to press eight days in advance of the date of issue. Therefore, in sending in copy, time should be allowed for setting up advertisements and for the sending and return of proofs. Advertising rates will be made known on request.

CHANGE OF ADDRESS.

In ordering a change of address it is important that both the old and new address be given.

REMITTANCES.

Remittances should be made by check, draft, registered letter, money or express order. Currency should not be sent, unless registered. Stamps in amounts under one dollar are acceptable. Make all checks, etc., payable to "Journal American Medical Association," except those for annual dues. These should be made payable and sent direct to the Treasurer, Dr. Henry P. Newman, 100 Washington Street, Chicago

The Journal of the American Medical Association

Original Articles.

THE RELATION OF ETHYL ALCOHOL TO THE NUTRITION OF THE ANIMAL BODY.*

WINFIELD S. HALL, PH.D., M.D.
Professor of Physiology, Northwestern University Medical School.
CHICAGO.

Within the past year much has been said and written about alcohol. The daily press, the school periodicals and the medical journals have abounded in articles treating of various phases of the alcohol question. Professor Atwater's calorimeter experiments and his arraignment of the school text-books, together with the controversy regarding the army canteen, have reopened afresh questions which were supposed to be practically settled.

Most extended and trustworthy experiments have been performed in respiration-calorimeters by numerous investigators in Europe, and several European governments have made exhaustive experiments with alcohol in their armies; but a scientific question is never settled as long as new evidence is forthcoming, and all fair-minded people are open to conviction on all controversial questions.

The writer brings report of no new experiments; but attempts simply to discuss work done by others and to determine from these almost innumerable experiments and observations the relation of ethyl alcohol to the nutrition of the animal body.

So much work has been done in the last few years upon the subject of nutrition that it seems wise to give a brief résumé of the theory of nutrition as now understood by physiologists.

THE NATURE OF THE NUTRITIVE PROCESSES.

No adequate or acceptable theory of nutrition can leave out of account the work of Hertwig and the still more recent work of Verworn and Wilson on the cell. Physiologists now universally believe that the cell is the scene of all vital processes. The essential processes of nutrition are the metabolic changes which take place within the cells of the body, all other steps of nutrition are either antecedent or succeedant accessories. The antecedent accessories of nutrition are the preparation of food, its mastication, its deglutition, its digestion, its absorption, its distribution by the circulatory system, and its selection by the individual cells from the capillaries direct, or from the tissue plasma.

The cytologists tell us that cell-protoplasm is not a homogeneous substance, but that it has a complex structure, and a chemistry as complex as its structure. The cell-plasm or cytoplasm is that portion of the protoplasm outside of the nucleus, whose substance is called nucleoplasm. The cytoplasm is composed of a reticulum (spongioplasm) whose meshes are filled with a liquid (cytolymph). Inclosed within the meshes of the reticulum are innumerable trophoplasts or plastids.

The part which the complex nucleus plays in nutrition is so little understood that a discussion of probabilities may be omitted from this brief paper.

All motor activity as well as all chemical activity seems to be the attribute of the spongioplasm and its associated microsomes and plastids. The function of the plastids is to build up starch, chlorrophyll, pigments, and probably many other substances from simpler compounds. In other words, it is known that plastids function in the building-up chemical process of anabolism. It is just as certain that the microsomes are also active in anabolism, because all secreting glands and all nerve-cells become more granular during rest, i. e., the granules are replenished by anabolic processes. When motion has been observed it is the spongioplasmic threads and fibers that are manifestly the active agents, while the cytolymph, which fills the meshes of the spongioplasm, is perfectly passive.

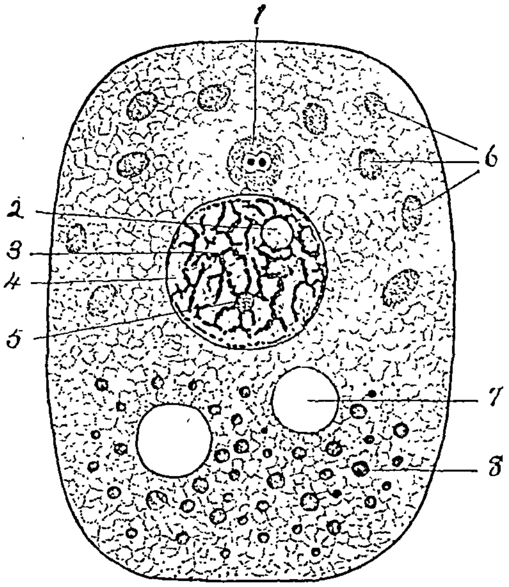

Diagram of a cell. (After Wilson.) The protoplasm of the cell may be divided into cytoplasm (cell-plasm) and nucleoplasm. Note that the cytoplasm is composed of a network (spongioplasm) in the meshes of which there is the clear cytolymph. The supposed relation between *spongioplasm and cytolymph is discussed* in the text.

1. Attraction Sphere inclosing the Centrosomes.
2. Plasmosome or true nucleolus: 3. Chromatin-network: 4. Linin-network: 5. *Karyosome or net-knot.*—Nucleus.
6. *Plastids lying in the cytoplasm.*
7. Vacuole.
8: Lifeless bodies (metaplasm) suspended in the cytoplasmic reticulum.

The observed facts indicate: That the spongioplasm is active and the cytolymph passive; that the spongioplasm and its associated microsomes [illegible] lastids a built up from the cytolymph, which is simply the cell-sap or cell-food; that the spongioplasm is a practically homogeneous living substance, while the cytolymph, representing the absorbed food-supply, is naturally a simple mixture of proteids, carbohydrates, fats and various salts, the whole made fluid by a large percentage of water.

---

*Presented to the Section on Physiology and Dietetics, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

All foods are selected by the cells from the surrounding medium and made a part of the cytolymph at first. Later they may or they may not be built up into spongioplasm. But in any case all foods are cell-builders, and if cell-builders, therefore, tissue-builders incident to their assimilation by the cell.

Physiologists and biologists[1] believe that all foods are built up into protoplasm; that is, they are selected and made a part of the living cell. That all of the dextrose and fats are actually built up into spongioplasm may or may not be true. If the dextrose is not anabolized into spongioplasm before it is oxidized, then the spongioplasm has the power of taking up the dextrose molecules and causing their oxidation, thus deriving heat energy; or, in the case of muscle-tissue, heat energy and motor energy.

There are strong reasons for believing that most of the dextrose is oxidized without being first built up into spongioplasm. If such is the case, then the relation of the living spongioplasm to the non-living cytolymph is that of an organized ferment to its medium. The spongioplasm may, therefore, be itself catabolized or it may act as a ferment and cause the catabolism of the foods of the cytolymph.

Now some of the cells of the body have to do work outside of their cell-body. The glandular cells of the alimentary tract secrete enzymes (unorganized ferments) which are poured out into the alimentary canal, where they induce hydrolytic cleavages of the ingested food-stuffs, thus preparing them for absorption and assimilation. A hydrolytic cleavage is a catabolic change. No anabolic changes may take place outside of living cells through the agency of secreted enzymes.

Among the catabolic changes which take place through secreted enzymes are oxidations. Under certain unusual circumstances sugar is oxidized in the blood by an enzyme called by Green[2] "oxidase." The body is constantly subject to the invasion of certain toxic substances like ptomains and various plant alkaloids. It has the power, within certain limits, of making these bodies harmless by oxidizing them. This is one of the protective agencies which the organism possesses. The system possesses two means of defence against harmful invasion: 1, the leucocytes defend it against bacterial invasion; 2, "oxidases," and, perhaps, other enzymes, in the blood defend it against ptomains, toxins, and allied deleterious substances. These defences are of inestimable importance to the organism, but their action is limited.

All intracellular catabolism is under the control of the organism because the action of each cell is controlled by the nervous system. All extracellular catabolism is independent of the nervous system and is, therefore, only indirectly under control. Once an enzyme is secreted it will continue to induce certain chemical changes as long as the physical conditions are favorable, wholly independent of the nervous system.

Having thus briefly reviewed some of the fundamental principles of nutrition, it is necessary that we next outline some of the conditions which a true food must fulfill.

WHAT IS A FOOD?

It is probable that in no other concept which man may wish to define does he get so much assistance from Nature as in the case of the term "food." In fact, Nature gives a very clear-cut and unambiguous definition of a food. Fortunately, she repeats this definition for every different branch of the plant and animal kingdom, so that there shall be no misunderstanding.

Nature says that the food for young mammals shall be milk. What is milk and what office does it serve in the body of young mammals? Milk consists of two kinds of protein, of fat, milk-sugar, inorganic living cells of the young growing body, and built up by them into living cell-protoplasm. Incident to the vital processes of the young mammal, portions of the cell substance are constantly being catabolized, or decomposed into simple substances. Oxygen plays an important rôle in this catabolism, and energy is liberated in the form of heat, or mechanical motion, or nervous energy, or secretory energy. Under the influence of this food the young mammal increases in size and strength.

Nature says that the food for young birds, reptiles, frogs, and fishes shall be eggs. Eggs consist of protein, of fats, of inorganic salts and water. Egg material is able to furnish all that the young bird, reptile, frog or fish needs for the early stages of his growth and development. The protein furnishes the nitrogenous compounds necessary for building up the active portion (spongioplasm) of every living cell, while the fat furnishes a non-nitrogenous portion of food, also taken within the cells of the growing animal and used there, by the active protoplasm of the cells. Eventually it is oxidized and yields its energy to the body as active heat or motor energy.

Nature's food for the young corn-plants is the matter stored away in the corn-grain by the mother-plant. This food consists of protein, carbohydrates, fats, inorganic salts and water.

For each of the different organisms mentioned above Nature supplies only one source of food. The young mammal has no alternative. It must take milk or starve. The young bird or reptile must take egg or nothing. When we subject the animal body to chemical analysis we find that it is composed of water and solids; we find that the solids are in turn composed of organic and inorganic compounds; the former comprising proteins, carbohydrates, fats, with various extractives representing products of tissue decomposition not yet excreted from the system when the animal met death. The inorganic salts represent the mineral matter of the bones, the salts of the blood and lymph, as well as the of the tissues in general. If we make analyses of various animal organisms we shall find the tabulated results strikingly similar for all classes of animals. If we make analyses of various foods which Nature provides for the young of these various animals we shall find, 1, that there is a striking qualitative similarity in the analyses; and 2, that the food analyses are strikingly similar to the analyses of the animals which they are to nourish—whole tissues they are to build up or to repair.

These coincidences are not the result of chance. Nature follows laws graven in the very foundation of living matter. Protoplasm can use as food only substance which it can bring within its cell-walls as a constituent of cell-sap (cytolymph). Though the food-stuff forms a portion of the cytolymph of the cell, it must still undergo anabolic or assimilative changes before it becomes a part of the living, moving, active, spongioplasm of the cell.

Are we now in a position to define a food in harmony with Nature's definition? Let us not attempt a brief word formula, but simply state a few of the conditions which a food must satisfy.

1. A food must be digestible and absorbable by the organism which it is to nourish.
2. A food must be assimilable by the living cells of the organism which it is to nourish. By these cells it is first made a constituent of the cytolymph, where it is held in temporary reserve for use by the acting, moving, spongioplasm, or, perhaps, by the nucleus of the cell. Incident to the assimilation of a food it will build up new tissue. It is customary for physiologists to differentiate between the building-up of new tissue and the repair of old tissue. This distinction is wholly gratuitous and unnecessary. New protoplasm is being built from the foods of each meal, old protoplasm is being catabolized or decomposed constantly. If the new protoplasm formed balances the old protoplasm decomposed, it is said that "the repair balances the waste." If the accretion exceeds the excretion, it is said that "the wastes are repaired and there is a balance for growth."
3. All assimilated foods, i. e., all living tissues, undergo catabolic changes accompanied by oxidation. This is nearly the equivalent of saying all assimilated foods are oxidized within the body; yet there is an important technical difference which makes the first statement more acceptable to the physiologist.
4. All of the energy which the animal organism can advantageously use is liberated incident to the catabolism of assimilated foods.
5. The energy which a food supplies must be liberated at such a time and place as to be beneficial and advantageous to the organism.
6. No substance can be recognized as a food which is not properly absorbable and assimilable, and whose catabolism or oxidation is not so controlled in time and place —i. e., co-ordinated—as to be advantageous to the system.

Let me quote the great physiological chemist, Bunge, on this point[3]: "It is not enough to prove that potential chemical energy is changed into kinetic energy. The oxidation must take place at the right place, i. e., at exactly the right stage in the activity of particular tissue-elements. It must be demonstrated that the kinetic energy liberated can be utilized in the performance of a normal function, otherwise the substance oxidized is not a food."

WHAT IS ALCOHOL?

It is unnecessary to discuss the chemistry of alcohol before this audience. It is universally recognized that its chemical formula and its various chemical relations are sufficiently different from those of any of the recognized foods that it must be put into a class by itself if it is admitted into the select company of the foods.

It is the essential nature of alcohol that I wish especially to discuss here. Alcohol is formed from sugar by the yeast plant. The yeast plant is a fungus. No fungus is able to build up organic substances from inorganic ones; that function is performed by green plants alone. Fungi (and bacteria) live upon the same substances as those that form the food of animals. Their metabolic processes are similar to those of animals. The yeast plant eats sugar and assimilates it into its cell protoplasm. It catabolizes this differently under different circumstances. If there is an abundance of oxygen the yeast plant will grow and multiply rapidly and will give off much more carbon dioxid than alcohol proportionately, showing that the sugar is in part used in building up new cell-substance and in part is completely oxidized to carbon dioxid and water. There is always some alcohol produced and the amount increases very much when the oxygen is shut away from the yeast—as is the case in the large beer and wine vats.

Dumas, the French chemist, writing in 1843, said: "Fermentations are always phenomena of the same order as those which characterize the regular accomplishment of the act of animal life. They take possession of complex organic substances and unmake them at once or by degrees." Trouessart[4] said, in 1886, that this statement of Dumas' had been "confirmed and no one now doubts it."

Dr. Josef Bersch[5] makes these statements: "Alcoholic fermentations can take place only in those fluids which are able to furnish for the yeast all of those substances which are necessary for its nourishment. The nourishing fluid passes into the body of the yeast-cell and the nutriment which is contained in the liquid is assimilated by the cell-protoplasm. Every yeast-cell gives up substances to the surrounding medium, which substances can only consist of such compounds as are of no further use to the organism, i. e., they are the *excreta*. . . . The yeast-cell excretes alcohol, carbon dioxid and other substances."

In his "Studies on Fermentation" Pasteur coincides with the above theory except that he believes that the yeast takes up the sugar in order to appropriate its oxygen. He did not, however, make it evident from a chemical staindpoint that this would be possible. We readily see that the decomposition of the sugar into the two simple products, alcohol and carbon dioxid yields a certain amount of energy. It is the energy that the yeast is after and not the oxygen. Pasteur admits this as alternative to his original hypothesis.

Pasteur[6] reports a most significant observation upon fruit kept in an atmosphere of carbon dioxid for eight days. The sugar of the fruit had been largely decomposed into alcohol and carbon dioxid and the 24 plums yielded 6.5 gm. of alcohol on distillation.

Lechartier and Bellamy[7] repeat Pasteur's experiments with fruit in an atmosphere of carbon dioxid, confirm his results and consider "that the formation of alcohol in fruits in an atmosphere of carbon dioxid may be attributed to the fact that the processes of life in the cells of fruit continue under new conditions similar to those of the cells of a ferment. If the fruit be crushed, before immersion in carbon dioxid, the production of alcohol and carbon dioxid will not occur, because the life of the cells has been destroyed."

Sims Woodhead, the Director of the Laboratories of the Royal College of Physicians, London, in his work on "Bacteria and their Products," recognized the analogy between alcohol and the ptomains. Aitken, writing on "Animal Alkaloids," brought out the fact that the bacterial decomposition of albuminous matter in absence of oxygen produces toxic leucomains. Let us not forget in this connection that the decomposition or catabolism of sugar by yeast, in absence of oxygen, produces alcohol.

Vaughan[8] says: "When ptomains are formed in the presence of a little oxygen they are poisonous; when formed in the presence of a free supply of oxygen they are invariably non-poisonous." "They—the cells of the body as well as bacteria—are injured when the products of their own activity accumulate about them." Also, "It is true without exception as far as we know that the excretions of all livi[illegible] is and [illegible]ntain substances [illegible] is to t[illegible] which excrete them. These poisons originate in the metabolic changes by which the complex organic molecule is split up into simple compounds."

Verworn[9], in discussing fermentation, gives the following equation as representing the decomposition of dextrose in alcoholic fermentation:

$$C_6H_{12}O_6=2C_2H_5.OH+2CO_2.$$

Now the carbon dioxid rapidly escapes from a fermenting liquid, but the alcohol accumulates, poisons the yeast plants and stops their activity.

It has been found that over 5 per cent. of the sugar consumed does not appear as alcohol and carbon dioxid and further that the quantitative equivalent of about 4 per cent. appears as glycerin and succinic acid, while 1 per cent. is unaccounted for.[10] Succinic acid is a poisonous ptomain (leucomain) belonging to the oxalic acid series.

Not only will the excretion of any living organism poison the organism which produces it but it will poison any organism of higher rank and some organisms of lower rank. Thus the excretion of a mammal might serve as food for some of the lower invertebrates and certainly for fungi and bacteria, while the excreta of the yeast fungus serves as pabulum for the bacterium of acetic acid. The excretion of the bacteria—ptomains—and of the yeast plant—alcohol—are poisonous to all higher organisms, in the very nature of the case.

We have found that higher animal organisms possess a means of defense against ptomains, alcohol and similar toxic substances: they oxidize them in the blood through the agency of a circulating enzyme, oxidase; this means has, however, its limitations.

THE RELATION OF ALCOHOL TO NUTRITION. IS ALCOHOL A FOOD?

W. O. Atwater, Professor of Chemistry at Wesleyan University, Middletown, Conn., and head of the work being done in the Government Experiment Stations on the Chemistry of Foods, has arraigned the school textbooks of physiology before the American people on the charge of falsehood, because these books teach the boys of America that alcohol is a poison and not a food, while his experiments with men shut up in a calorimeter demonstrate to his satisfaction that "alcohol is a food" and " not a poison, in moderate quantities." Professor Atwater's definition of food is, "That which taken into the body builds tissues or yields energy." Note especially the alternative between tissue-building and energy-yielding. According to this experimenter, any substance is a food if it is oxidized "in the body" anywhere between the mouth and the excretory surface. Not since the days of Liebig, a half-century ago, have the bars that set a boundary to foods been so ruthlessly torn down. Even iron filings and phosphorus satisfy the terms of this definition; and a long list of ptomains, leucomains, and toxins come clearly within the definition. Here is a list of a few of the substances which satisfy Atwater's definition of a food: Succinic acid $(COOH)_2.(CH_2)_2$ oxidized to CO_2 and H_2O; asparagine $(CONH_2.C_2H_3.NH_2.COOH)$ and glutaminic acid $(COOH)_2—(CH_2)_2—CHNH_2)$ both oxidized to urea, water and carbon dioxid. Chinolin (C_9H_7N) is oxidized similarly. Tyrosin[11] $(C_6\ H_4.OH—C_2H_3NH_2—COOH)$ is oxized to phenol, H_2O, CO_2 and NH_3.

Blyth, in his admirable new work on poisons, gives the following toxins as frequent causes of death: Muscarin, $(CH_2OH—CHOH—N—(CH_3)_3.OH$, also neurin $(CH_2—CH—N—(CH_3)_3.OH.)$ Both of these are intensely poisonous and both are oxidized in the system.[12]

Meta-phenylene-diamin $(C_6H_4—(NH_2)_2$ and also para-phenylene-diamin are both poisonous and are both oxidized in the animal body. Morphin is also oxidized in the body.

It is unnecessary to carry the list further; these substances, though more complex than ethyl alcohol, are closely related to it physiologically.

Liebig classified foods as "plastic" and respiratory," i. e., as tissue-builders and energy-producers. No authoritative modern work on physiology recognizes any distinction between these two functions of food. The teaching of modern physiology is: *All food is tissue-building in its assimilation; all food is energy-yielding in its catabolism.*

Atwater admits that the only points that alcohol possesses in common with the foods are: 1, it is oxidized within the body; 2, it decreases carbonaceous and perhaps also proteid catabolism. This is called the "sparing" action of alcohol and is alleged to entitle alcohol to a place among foods. In demonstrating these two points, Professor Atwater is simply confirming what has been known for at least twenty years, so that he has added no new facts to science in his calormeter experiments. He has simply accumulated evidence of facts that have long been generally recognized. Upon the basis of his experiments he has set up the old and oft-refuted claim that alcohol is a food.

To quote a recent editorial[13] of The Journal of the A. M. A.: "The fallacy of the reasoning which would place alcohol among the foods is very apparent when we put it in the form of syllogisms: All foods are oxidized in the body; alcohol is oxidized in the body; therefore, alcohol is food. As logically we might say: All birds are bilaterally symmetrical; the earthworm is bilaterally symmetrical; therefore, the earthworm is a bird. Oxidation within the body is simply one of several important properties of a food, as bilateral symmetry is one of several important characters of a bird."

If we admit alcohol to a position among the foods on the simple grounds of oxidation we must also admit numerous substances universally acknowledged to be toxic.

There are a number of medical writers who speak of alcohol as having "a limited food value" because of its oxidation in the body. It would be just as reasonable to contend that because an earthworm is bilaterally symmetrical it is, therefore, to a limited extent a bird!

There is a good deal of misinterpretation and misapprehension regarding the significance of certain of the effects of alcohol upon the vital activity of the cells. It has been determined, for example, that after the ingestion of alcohol the excretion of carbon dioxid is diminished. This is accompanied by an accumulation of the carbonaceous materials of the body, and the actual deposit of fat or a sparing of protein, one or the other of these latter effects being certain to follow any cause which will decrease the excretion of carbon dioxid. Many jump at once to the conclusion that any substance which can cause a sparing of protein or of fat or both must of necessity be a food. But that conclusion does not by any means follow. There is a very closely veiled fallacy in the course of reasoning which leads to such a conclusion, and many have passed it by without recognizing it. That is especially the case with those who take account of ingesta and egesta alone, without trying to follow the changes which take place within the cells.

Let us unveil the fallacy. Under conditions of normal activity a cell will catabolize—or, we may say, oxidize—a certain amount of matter drawn immediately either from the cell-sap or from the living cell-substance itself. This matter is in part nitrogenous and in part non-nitrogenous. All food is "tissue-building" in its assimilation, and all food is "energy-liberating" in its oxidation. To arbitrarily differentiate between tissue-building and energy-liberating is wholly unwarranted in the light of modern research in cell physiology. So the cell under normal conditions will oxidize a certain amount of its matter. This oxidation will yield the energy required for the vital processes, and will also yield certain products of decomposition. The non-nitrogenous molecules will, on oxidation, yield carbon dioxid and water; while the nitrogenous molecules will yield carbon dioxid, water and urea or allied nitrogenous excreta.

Let us suppose that the cell is in a condition of carbon and nitrogen equilibrium, i. e., that it gives out daily in its excreta an amount of carbon and nitrogen equal to that of the food which it assimilates. If under these conditions a little more food be absorbed by the cell, one or the other of two things will happen; either there will be a greater cell-activity—muscular, nervous or secretory—with a correspondingly greater output of carbon dioxid with some increase in the nitrogenous excreta; or there will be an accumulation of fat or protein within the cell. The cell-activity being governed by the central nervous system rather than by the simple presence of increased food, the second alternative will be the one most uniformly observed. That is, if we give more food, we will get an accumulation of the excess as a reserve. Now suppose that without any excess in the food-supply the central nervous system causes a decrease of cell-activity throughout all of the active tissues, there will be an accumulation of unused food materials within the active cells or within the storage tissues. This nervous influence upon the oxidation of food materials may be produced by morphin. After the administration of morphin there will be an accumulation or a "sparing" of both carbonaceous and protein food materials, or tissues, providing the ingested food is normal in amount. Boecker[14] found, by experiments upon dogs, that after the animals were brought into a condition of nitrogen equilibrium, the administration of morphin with the food in a quantity to produce its typical physiologic effect caused the proteid catabolism to be decreased 6 per cent., and the excretion of carbon dioxid was decreased 27 per cent.

If we were to take into account simply the balance of ingesta and egesta we might reason thus: The addition of food to an animal in carbon and nitrogen eqilibrium leads to an accumulation of carbon and nitrogen in reserve, all other things remaining the same. The addition of morphin to the food of an animal in carbon and nitrogen eqilibrium leads to an accumulation of carbon and nitrogen in reserve, all other things remaining the same. Therefore, morphin must be a food.

The fallacy of this reasoning is apparent only when we take into consideration the vital process of the cell. Morphin depresses the activity of the cell, oxidation is decreased, less cell-substance is decomposed, the amount of matter absorbed remaining the same, there must be an accumulation of carbon and nitrogen in the cell. Notice the difference between the two cases: With increased food, the activity remains the same or is increased and the result is an accumulation of carbon and nitrogen or greater activity with increased carbon dioxid and nitrogen excretion. With the influence of morphin, the activity is always decreased, and the excretion of carbon and nitrogen is always decreased. With both there is an accumulation of food materials or of cell-substance; thus the final chemical effect of morphin is similar to that of increased food ingestion. But the total effect upon the vital processes within the cells is as nearly opposite as it is well possible to be: Increased activity and increased excretion with increase of food; but decreased activity and decreased excretion with morphin.

Morphin is a narcotic. All narcotics depress vital activity. Brunton, Cushny, Blyth, and all the newer authorities on pharmacology and toxicology agree that alcohol is a narcotic in both small and large doses. All who have experimented with alcohol in its relation to the output of carbon dioxid agree that it is diminished. This result is in perfect harmony with the general narcotic effect, and simply means that cell-activity is diminished.

To demonstrate that alcohol "spares carbonaceous and protein foods and tissues" is simply to prove that it is narcotic in its effect upon cell-activity unless it can be demonstrated that the consumption of oxygen and the output of carbon dioxid are either normal or increased. But these gases are always decreased in their interchange, after ingestion of alcohol in even moderate quantities. Alcohol then can not be a food; it is a narcotic.

Listen to the testimony of Austin Flint[15] upon this question: "The immediate effects of the ingestion of a moderate quantity of alcohol, continued for a few days, are decided. It notably diminishes the exhalation of carbon dioxid and the discharge of other excreta, especially urea. Proper mental and physical exercise and all conditions which favor the vigorous nutrition and development of the organism physiologically increase rather than diminish the quantity of the excreta. They correspondingly increase the demand for food, and if continued are of permanent benefit. Alcohol, on the other hand, *diminishes the activity of the nutrition.*"

Rolleston[16] says that "alcohol forms with the hemoglobin of the red blood-corpuscles a compound which takes up and parts with oxygen less readily than normal hemoglobin. This leads to a general diminution in the metabolism of the body and as a result the amount of fat in the body may become increased. . . Partly as a result of its action as a functional poison on the tissues of the body (especially the nerve cells, mentioned in an accompanying paragraph) and partly from its influence on hemoglobin, the metabolism of the tissues is diminished by alcohol."

It is thus demonstrated on indisputable grounds that the only two claims that the friends of alcohol have advanced for its recognition as food are based upon misinterpreted facts, and an archaic misconception of fundamental biologic and physiologic principles, and that the whole argument for alcohol is a superstructure of fallacies hardly less notable, when we consider the men who have lent their names and their reputations as scientists in a vain attempt to gain them credence, than the notorious "Moon Hoax" or the often advanced and as often refuted "Spontaneous Generation" fallacy.

HOW ALCOHOL INFLUENCES CERTAIN PHASES OF METABOLISM.

We may close the case against alcohol by making a very brief presentation of some of the effects of alcohol on some of the most important manifestations of life.

ALCOHOL AND BODY-TEMPERATURE.

Professor Atwater follows Liebig of a half-century past in placing alcohol among the heat-producing foods. We must all agree that alcohol is largely oxidized in the body to carbon dioxid and water. It yields just as much heat incident to its oxidation in the body as it would if oxidized outside of the body; so do morphin, the ptomains and the toxins. But the case is stronger against alcohol and morphin than against the ptomains and toxins because the narcotic action of alcohol on the cutaneous vasomotor system causes the temperature of the body to fall, notwithstanding the added heat from the oxidation of the alcohol. When given in doses that produce the flushing of the cheeks, very moderate doses by the way, there will always be a fall in body-temperature slight or marked, commensurate with the dose. This effect is produced through the combined action of alcohol upon the heat-generating factor as well as upon the heat-dissipating factor of body-temperature.

As above stated, alcohol lessens cell-activity and thus lessens the generation of heat by the active tissues. Von Bunge says:[17] "Even if alcohol does on the one hand increase the heat-formation through its own oxidation, it, on the other hand, increases the heat radiation. Through the paralyzing action which it exerts upon the vasomotor centers there occurs a dilatation of the vessels, especially those of the skin, and this leads to increased loss of heat. The total result is, in any case, a lowering of body-temperature which has been conclusively demonstrated."

Landois[18] mentions the danger of taking either alcohol or morphin when the body is to be subjected to extreme cold. All Northern explorers know that the use of alcohol endangers life through the cooling of the body. Brunton[19] tells a well-authenticated incident in this connection: "A party of engineers were surveying in the Sierra Nevadas. They camped at a great height above the sea level where the air was very cold and they were chilled and uncomfortable. Some of them drank a little whiskey and felt less uncomfortable; some of them drank a lot of whiskey and went to bed feeling very jolly and comfortable indeed. But in the morning the men who had not taken any whiskey got up in good condition; those who had taken a little whiskey got up feeling very miserable; the men who had taken a lot of whiskey did not get up at all; they were simply frozen to death. They had warmed the surface of their bodies at the expense of their internal organs.'

ALCOHOL AND MUSCULAR WORK.

It has been so frequently demonstrated that alcohol in even moderate doses impairs the muscular action both in power and agility that all athletes abstain totally from it during training as well as during the contests. Prize fighters, though plying their trade especially in the interests of the drinking and gambling element of society, are not allowed an ounce of whiskey or brandy for weeks before a contest.

Several European governments have made comparative tests of sugar and of alcoholic drinks for soldiers on forced marches. These tests have invariably resulted in alcoholic drinks being withheld during all strenuous work and sugar or sweet chocolate being given with the rations for such occasions.

Leitenstorfer's[20] extensive experiments on sugar and alcohol resulted in recommendation to the commissariat of the German Army—later adopted in the main—that sugar be used: 1, as a supplementary article to improve the daily rations of the soldier; 2, as a reserve supply in ships; and, 3, as a temporary ration to strengthen the soldiers and sustain their vigor while on the march.

The *Revue Scientifique*, in commenting upon the experiments of Leitenstorfer, says: "Sugar appears to be indicated to replace alcohol or wine under the various conditions when it is commonly considered desirable to include the latter in rations. Sugar affords stimulation, but without any danger. It has, moreover, the incontestable advantage of being a muscular aliment of the first rank, combating and at the same time preventing fatigue."

Bunge[21] says of these "army experiments:" "Better than through all the laboratory experiments and deductions is the demonstration of the complete uselessness, indeed harmfulness, of even the most moderate doses of alcohol, which demonstration has been made through the thousand-fold experiments by the commissariat of the army and which have already established conclusively that soldiers in times of peace and in times of war, in all climates, in heat, cold and rain, endure best all the fatiguing exertions of the most exhausting marches and maneuvers when they are absolutely deprived of all alcoholic drinks."

ALCOHOL AND THE WORK OF THE NERVOUS SYSTEM.

Even the most enthusiastic friends of alcohol admit that in more than moderate doses it is a narcotic poison to the nervous system. But the best and latest authorities all agree that its action upon the nervous system is always that of a narcotic, whether the doses be small or large. In this connection one needs only to cite such authorities as Brunton[22] of London, Edes[23] of Harvard, and Cushny[24] of Ann Arbor, all of whom state in unequivocal terms that alcohol is a narcotic in small, as well as in large, doses.

Brunton modified Francis Garton's instrument for measuring the speed of mental processes. As modified it measured: 1, the time required for simple reaction, i. e., the time to indicate the seeing, hearing, or feeling of a signal; (.18 sec.) 2, the time required for discrimination, e. g., to indicate whether one sees a red or a white object; (.24 sec.) 3, the time required for decision, i. e., whether to press one button or another in response to varying signals; (.36 sec.) Summing up the experimental work on this subject Brunton says: "Alcohol increases the reaction time, the time for discrimination and the time for decision. It makes all the nervous processes slower, but, at the same time, it has the curious effect of producing a kind of mental anesthesia so that all these processes seem to the person himself to be quicker than usual, instead of being as they really are much slower. Thus a man, while doing things much more slowly than before, is under the impression that he is doing things very much more quickly. What applies to these very simple processes applies also to the higher processes of the mind. A celebrated author once told me that if he wrote under the influence of a small quantity of alcohol, he seemed to himself to write very fluently and to write very well, but when he came to examine what he had written, the next day, after the effect of the alcohol had passed off, he found that it would not stand criticism."

ALCOHOL VS. FOOD IN NUTRITION.

In closing it will be interesting to set over against each other, in parallel columns, some of the demonstrated facts which we possess regarding alcohol and food in their relation to nutrition.

THE TRUTH ABOUT

ALCOHOL.	FOOD.
1. A certain quantity will produce a certain effect at first, but it requires more and more to produce the same effect when the drug is used habitually.	1. A certain quantity will produce a certain effect at first, and the same quantity will always produce the same effect in the healthy body.
2. When used habitually, it is likely to induce an uncontrollable desire for more, in ever increasing amounts.	2. The habitual use of food never induces an uncontrollable desire for it, in ever increasing amounts.
3. After its habitual use a suden total abstinence is likely to cause a serious derangement of the central nervous system.	3. After its habitual use a sudden total abstinence never causes any derangement of the central nervous system.
4. Alcohol is oxidized rapidly in the body.	4. All foods are oxidized slowly in the body.
5. Alcohol, not being useful, is not stored in the body.	5. All foods, being useful, are stored in the body.
6. Alcohol is a product of decomposition of food in the presence of a scarcity of oxygen.	6. All foods are the products of constructive activity of protoplasm in the presence of abundant oxygen.
7. Alcohol is an excretion and, in common with all excretions, is poisonous. It may be beneficial in certain phases of disease, but it is never beneficial to the healthy body.	7. All foods are formed by nature for nourishment and are by nature wholesome and always beneficial to the healthy body, though they may injure the body in certain phases of disease.
8. The use of alcohol, in common with narcotics in general, is followed by a reaction.	8. The use of foods is followed by no reaction.
9. The use of alcohol is followed by a decrease in the activity of the muscle-cells and the brain-cells.	9. The use of food is followed by an increased activity of the muscle-cells and brain-cells.
10. The use of alcohol is followed by a decrease in the secretion of CO_2.	10. The use of food is followed by an increase in the excretion of CO_2.
11. The use of alcohol is followed by an accumulation of fat through decreased activity.	11. The use of food may be followed by accumulation of fat, notwithstanding increased activity.
12. The use of alcohol is followed by a fall in body-temperature.	12. The use of food is followed by a rise in body-temperature.
13. The use of alcohol weakens and unsteadies the muscles.	13. The use of food strengthens and steadies the muscles.
14. The use of alcohol makes the brain less active and accurate.	14. The use of food makes the brain more active and accurate.

SUBSTITUTE INFANT-FEEDING.

HENRY DWIGHT CHAPIN, M.D.
Professor of Diseases of Children at the New York Post-Graduate Medical School and Hospital.
NEW YORK CITY.

The question of the home preparation of an infant's food is one that occasions more or less difficulty to the average practitioner. Very little disturbance of digestion is caused by average breast milk but when it comes to bottle-feeding, trouble often appears, and here the physician has abundant opportunity to show his knowledge of dietetics. There is no end to the number of the so-called "perfect substitute for mother's milk" that are widely advertised, but the mainstay of successful bottle-feeding is good cow's milk. Anything else must be only a temporary substitute. The infants who can not take properly prepared cow's milk are very rare. The trouble often comes from the inability of the physician to properly modify the milk, so as to make it suitable for the case in hand. It is impossible to lay down fixed rules for infant-feeding, as each case must be treated by itself, but there are certain underlying principles involved which, if understood, will greatly simplify the problem.

The important things to know are, first, how to secure good cow's milk, and, second, how to change or modify it so that it shall be as near as possible an approach to mother's milk in composition and digestibility. The first problem before the physician is to secure a supply of good fresh milk. This can be had anywhere, by the exercise of a little care. Let the cows be cleaned as thoroughly as horses, and the udders and sides wiped off with a damp cloth just before milking. Let the milking be done with clean, dry hands, into a clean pail, held close to the udder. The first stream or two from each teat should be thrown away, and not allowed to get into the pail, for during intervals between milking, bacteria from the air get into the cow's teats, and grow with wonderful rapidity. By throwing away the first few streams, at the beginning of the milking, these are disposed of. If the sides of the cow are plastered with dirt and manure, as is often the case, a certain amount is sure to fall into the pail of milk. This is where the trouble really begins, for this dirt and manure abounds in bacteria. Over two hundred species of bacteria have been found in milk, about twenty of which produce lactic acid. Other species produce ropy, slimy, blue and red milk, also alkaline products. These bacteria themselves are practically harmless, but the products of their growth may seriously affect the healthfulness of milk. Pathogenic bacteria are occasionally found in milk, but they get there almost invariably through the water used in washing the milk cans or bottles, or from the skin of some infected attendant. Tubercle bacilli are found in milk from cows with tuberculous udders, but the danger of infecting human beings is thought to be greatly overrated. Tubercle bacilli do not grow in milk.

As soon as each cow is milked, the milk should be run through an aerator and cooler, in a room free from bad odor or tobacco smoke, and then kept as cool as possible until used. It is obvious that cows should be stabled in clean, well-ventilated barns. These conditions should be possible everywhere, and if the physician will insist upon their observance on the part of dairymen, the problem of a proper milk-supply will be largely solved.

The prompt and rapid aeration and [illegible] of milk are matters of importance. The [illegible] which bacteria in milk grow most [illegible] body heat. There is practically no growth when the temperature is below 50 degrees F. It has been proved that bacteria which increased two hundred fold in four hours, at 93 degrees F., increased only eight fold at 55 degrees F., so the necessity of cooling the milk immediately after milking will be apparent.

Combined aerators, strainers and coolers, suitable for use with well-water or ice-water, can be had at any dairy-supply house, at a small cost. By using one of these, the cow odor, the animal heat, and most of the dirt can be removed from milk in a few minutes. The milk of a herd of cows can then be mixed and bottled, or canned and packed in ice, or, as is often done, lowered into a well or set in a cool spring. Such milk will keep well, while milk "warm from the cow" soon spoils.

Sometimes dairymen add preservatives to their milk, to keep it sweet. The articles most commonly used are boric acid, borax and formaldehyde. Formaldehyde is particularly objectionable, as it renders the curds exceedingly tough. It can be detected by adding to a small quantity of slightly diluted milk an equal quantity of commercial sulphuric acid. Pour the milk into a test-tube or flask, and then allow the acid to run in, so as not to mix with the milk. A violet color will appear at the junction of the two liquids, if formaldehyde is present, and the curd of the milk will dissolve slowly when the tube is shaken.

In selecting cow's milk for infant-feeding, that which is clean, aerated, cooled and bottled immediately after milking, and kept below 60 degrees F., until delivered, is the article to be chosen by the physician. The richness of milk and cream depends upon the breed of cattle supplying the milk. In most of the states that have dairy laws, the minimum amount of butter fat allowed in the milk is 3 per cent. In actual practice milk varying between 3 and 5 per cent. butter fat will be met.

In reference to the production of butter fat, cows may be roughly divided into three classes: 1. Fancy, full-blooded Guernseys and Jerseys, giving milk containing 5 per cent. and over; 2, ordinary Jerseys and Guernseys, known as "butter cows," giving milk containing 4 per cent. and over; 3, Ayrshires, Holsteins and common stock, known as "milk cows," giving milk containing 3 per cent. and a little over.

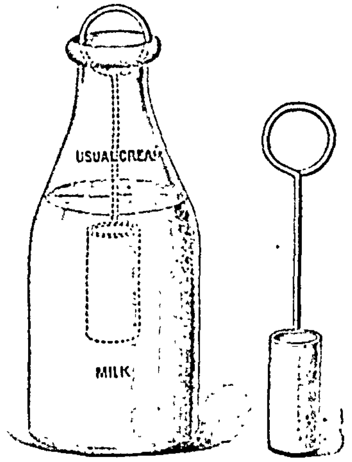
A physician in a given neighborhood should find out what breeds of cattle supply the milk to the vicinity, in order to know about the proportion of butter fat contained in the milk. The milk of one dairyman will run quite uniform from day to day, as the variations in the milk of individual cows will compensate each other.

In mother's milk the fat is usually between 3 and 5 per cent., or nearly three times the proteids, which vary from 1 to 2 per cent.; while the sugar is between 6 and 7 per cent. As noted above, cows' milk will contain from 3 to 5 per cent. butter fat, while the proteids average about 4 per cent., and the sugar from 4 to 5 per cent. It is pretty well settled that in mixed cows' milk, the proteids about equal the fat, when the fat does not exceed 4.5 per cent. When the fat in the whole milk is above 4.5 per cent. the proteids are a little less than the fat.

While in most cases, a medium grade of milk will be supplied, especially in towns and cities, still, we must be prepared to properly modify either very rich or poor milk. An easy way of calculating percentages, is to take advantage of the process known in the dairy industry as the "deep setting process of creaming." This consists in putting milk into tall, narrow vessels and cooling to about 40 degrees F. After twelve to twenty-four hours practically all the fat of the milk will be found in the creamy layer, the remaining milk often containing no more than .2 to .5 per cent. Milk that has been bottled and kept cool for twelve to twenty-four hours, is subjected to the conditions necessary for successful "deep setting" creaming, and usually contains a layer of cream in the neck of a quart bottle, between three and four inches deep, measuring from the top, or about six fluidounces. The line separating the cream from the remaining milk is distinct. Unless the creamy layer is distinct when the milk is delivered, it is probable that bottling has not been done at the dairy, but in the town or place of delivery. Not only is the proper creaming thus interfered with, but the chances of contamination are increased.

By taking all of the cream and part of the remaining milk from the quart bottle of milk and mixing in certain proportions, top milks, rich or poor in fat, can be had, that may be utilized in feeding the infant. Top milks can be prepared in which the fat is one and one-half to five times the proteids.

In the home modification of milk, by means of this bottled milk, the cream is readily and accurately separated from the remaining milk by means of a dipper measuring exactly one fluidounce. The first dipperful, or ounce, is taken off with a teaspoon, otherwise, the milk would spill over when the dipper is let down. The successive ounces of cream are then easily removed, by even an unskillful hand, without jarring, siphoning or other manipulation.



The following assays, made by the Babcock method, show the percentages of fat in different top milks, taken from quart milk bottles, and represent low, medium and high grade milk, which was bottled in the country:

Fat in whole milk	3.1	4.3	5
Fat in Top 9 ounces	9.2	12.4	14.6
Fat in Top 10 ounces	8.37	11.2	13.2
Fat in Top 11 ounces	7.7	10.4	12.1
Fat in Top 12 ounces	7.0	9.6	11.1
Fat in Top 13 ounces	6.6	9.0	10.4
Fat in Top 14 ounces	6.2	8.4	9.7
Fat in Top 15 ounces	5.8	7.9	9.0
Fat in Top 16 ounces	5.5	7.5	8.6

Proteids and sugar are assumed to be 4 per cent. each.

It will be noticed that the first nine ounces or dipperfuls contain about three times as much fat as the whole milk in all three grades. This rule held good in thirty quarts of bottled milk on which the cream had risen, obtained of different dealers.

For matter of easy calculation, it is assumed that the proteids and sugar are 4 per cent. each. In practice, all that is necessary is to dip off top milk of any desired richness, and dilute it, two, three, four, five, six or eight times. If about 3 per cent. of fat and 1 per cent. of proteids is desired, nine ounces will be dipped out of the bottle of milk on which the cream has risen. If it is poor, bluish-colored milk, it will be diluted three times, that is, one-third of the desired mixture will be top milk. If the milk is of a fair degree of richness, it will be diluted four times—one-quarter of the desired mixture will be top milk. If the milk is very rich, it will be diluted five times—one-fifth of the desired mixture will be top milk. By dividing the figures in the table by the dilution, average percentages will be obtained. This is as near to accuracy as percentage feeding can be brought at home, and is sufficient for the vast majority of cases. The proper percentages for each child are obtained by increasing or decreasing the richness and the dilution of the top milk. What is needed in a given case is a dilution of cow's milk that will agree with the baby we are trying to feed, rather than the procuring of figured percentages. By this method every physician can vary the strength of the milk in a sliding scale by directing the number of ounces to be dipped out of the bottle of milk, and thus tentatively reach the strength that is suitable for the infant's digestion.

For every twenty or twenty-five ounces of food, add one ounce of sugar, in order to bring this element up to the proper proportion. One part of sugar to 20 parts of food yields 5 per cent; to 25 parts, 4; to 33 parts, 3; to 50 parts, 2 per cent. An even tablespoonful of granulated sugar equals half an ounce approximately, and one scant teaspoonful equals a dram. Half again as much milk sugar equals the same weights.

The next important step is to get the cow's milk as nearly as possible in the same physical condition as mother's milk. The diluent I prefer to use is a wheat, barley or oatmeal gruel, the starch of which has been digested or dextrinized by the action of diastase. A heaping tablesponful of flour, made from a cereal, is boiled with about a pint and a half of water for fifteen minutes. It is then removed from the stove and set in cold water for about three minutes to cool it. When it is sufficiently cool to taste, a teaspoonful of a preparation of diastase is added, which renders the gruel thin and watery. This makes about a pint of gruel, containing the starches in soluble form, while the cellulose or skeleton of the cereal acts as a most effective attenuant of the curd. These digested gruels render the milk curds porous, and also provoke the secretion of the digestive juices. As diluents, they are a great improvement on water. Most of the thick malt extracts are sufficiently active in diastase to produce the desired effect. The writer, however, prefers the employment of diastase itself, without any of the other malt ingredients, as being both speedy and efficient. It can either be produced cheaply at home, or purchased at the nearest drug store. A simple decoction of diastaste may be made as follows: A tablespoonful of malted barley grains is put in a cup, and enough cold water added to cover it, usually two tablespoonfuls, as the malt quickly absorbs some of the water. This is prepared in the evening and placed in the refrigerator over night. In the morning the water, loking like thin tea, is removed by a spoon or strained off, and is ready for use. About a tablespoonful of this solution can be thus secured, and is very active in diastase. It is sufficient to dextrinize a pint of gruel in ten to fifteen minutes. Preparations of diastase are made by a number of chemists—Forbes, Parke Davis & Co., Horlick and others. There is now obtainable an active glycerite of diastase known as Cereo, which is specially made for the purpose of dextrinizing gruels.

Now the question of Pasteurization—heating to 167 degrees F.—or sterilization—heating to 212 degrees F. —arises. It should be remembered that the object of Pasteurizing and sterilizing milk is to kill the bacteria, and in that way make the milk suitable for infant-feeding. If the milk was originally clean, cooled immediately after being drawn, and kept cool, there would be no need of heating the milk to kill bacteria. In the summer time, where it is impossible to keep the milk below 60 degrees F., it is best to have it Pasteurized as soon as it is received.

It is often recommended that lime-water or bicarbonate of soda be added to milk, when it is slightly acid. The acidity of milk is caused by bacteria that produce lactic acid. If the acid is neutralized, the bacteria will produce more acid, unless the milk is either kept cool or heated to destroy the bacteria.

There are cases constantly arising where milk must be withheld for a time, or given only in small quantities. Here is where the judgment of the physician may be put to a severe test. The symptoms that call for a modification or a change of diet, are vomiting, colic, and unnatural stools. A brief glance at these conditions may be helpful to some in applying dietetic remedies.

Vomiting.—When vomiting occurs immediately after feeding, it is probably caused by a simple distension of the stomach, and less bulk of food is accordingly indicated. The vomiting that occurs some time after feeding is apt to be caused by undigested food, the rejections are frequently highly acid, and there may be curds and mucus present. Projectile vomiting, where food is rejected with force, is an indication of brain irritation.

Colic.—Colic may be caused by cold, but is more frequently induced by the fermentation of indigestible food.

Condition of the Stools.—Much may be learned by a careful inspection of the stools, with reference to increasing or diminishing the various kinds of food. The normal infant stool is smooth, yellow, homogeneous, and about the consistency of thin mush. The following may be considered abnormal types:

1. Green Stools.—Stools can only be considered green when that condition is evident immediately upon their passage. They are due to a fermentation, which is doubtless the result of bacterial action. All stools become green a certain time after passage, caused by oxidation of the air.

2. Curdy Stools.—Curdy lumps may be produced by undigested casein or fat. The former are hard and yellowish, while the latter are soft and smooth, like butter.

3. Slimy Stools.—These are the result of catarrhal inflammation. When the mucus is mixed with the fecal matter, the irritation is high up in the bowel, but when flakes or masses of mucus are passed, the trouble is near the outlet.

4. Yellow, Watery Stools.—These are seen in depressed nervous conditions, especially in the hot days of summer, when the bowel is relaxed, and the inhibitory fibers of the splanchnic nerve do not act to advantage.

5. Very Foul Stools.—These are caused by decomposition of the albuminoid principles of the food.

6. Profuse, colorless, watery stools, with little fecal matter, are doubtless caused by an infective germ, akin to that of Asiatic cholera. This is known as *cholera infantum.*

It is rare to see one of these types by itself. With the exception of the last, they may be seen in all combinations.

In slight forms of unnatural stools, increase the dilution of the top milk, and reduce the quantity of sugar slightly. If large lumps of fat are in the stools, use milk containing less fat for diluting; this can be obtained by taking more top milk out of the quart bottle. Where lumps of casein are apparent, the diluent must be increased. If increasing the dilution and reducing the fat and sugar does not overcome the trouble, stop the milk and feed dextrinized gruel for a day, gradually adding a little milk, which is increased in amount as fast as the infant can digest it.

There are times when infants can not digest milk in any form, no matter how much it may be diluted, nor what diluent is employed. They may then be given mutton broth, from which the fat has been removed, extracted beef-blood and water, dextrinized wheat or barley gruel, or dextrinized gruel, to which either the white or yolk of an egg has been added.

The following will show the food principles obtained by such egg mixtures:

Dextrinized gruel and white of egg.—Dextrinized wheat-flour gruel, 8 fluidounces, white of one egg—581 grains (large egg).

About 2 per cent. proteids (egg 1.25, gruel .75), 4 per cent. soluble carbohydrates.

Putting two even spoonfuls of granulated sugar into this mixture, 3 per cent. of sugar is added, which, with the 4 per cent. of digested starch, makes 7 per cent. total soluble carbohydrates.

White of egg contains 85 to 88 per cent. water; .07 per cent. salts; 10 to 13 per cent. proteid bodies, made up of albumin, gobulin and mucoid substance and traces of fats, lecithin and cholesterin.

Dextrinized gruel and yolk of egg.—Dextrinized wheat-flour gruel, 8 fluidounces, yolk of one egg—288 grains (large egg.)

About fat 1.7, proteids 1.7, (egg 1., gruel .70) and 4 per cent. soluble carbohydrates.

By putting two even spoonfuls of granulated sugar into this mixture, 3 per cent. of sugar is added, which with the 4 per cent. of digested starch, makes 7 per cent. total soluble carbohydrates.

Yolk of egg contains about 47.19 per cent. water and 52.81 per cent. solids, made up of 15.63 per cent. proteids, .96 per cent. salts, 22.84 per cent. fat, 10.7 per cent. lecithin and 1.75 per cent. cholesterin. Proteids of yolk contain phosphorus and iron, which is of great importance in the formation of blood, and a pseudonuclein which is also found in casein of milk. These are not present in the proteids of the white of egg. Lecithin, which also contains phosphorus, is undoubtedly "a very important material for building up of the complicated phosporized nuclein substance of the cell and cell nucleins." Lecithin is also found in milk, especially woman's milk.

THE SPECIFIC TREATMENT OF CROUPOUS PNEUMONIA.[*]

WILLSON O. BRIDGES, M.D.
OMAHA, NEB.

The mortality of croupous pneumonia is greater than that of any other acute disease; higher than that of diphtheria, and next below that of tuberculosis. The mortality statistics in private and hospital practice show a percentage of from twenty to forty. The census of 1890 indicated that 76,496 persons died of pneumonia in the United States during the preceding year, a death-rate of 186.94 per 100,000 of population. The census reports of 1870, 1880 and 1890 show that the deaths from this disease have slightly increased. It is the most wide-spread of all acute diseases.

It is nearly twenty years since Fränkel discovered the diplococcus lanceolatus and established its causative relation to croupous pneumonia, since which time renewed efforts have been, and are being, made for the discovery of a specific prophylactic and curative agent. Some years ago the Klemperers demonstrated that the injection of blood-serum, obtained from one who had recently recovered from pneumonia, conferred immunity in some of the lower animals, and it was hoped that an antitoxic serum would be obtained which would be prophylactic and curative in man. While some favorable results from the injection of 20-c.c. doses have been reported by a number of observers, the treatment has not as yet gained a foothold. Various drugs have been from time to time advocated as specifics; long before the antimicrobic theory of treatment was suggested, calomel in large doses—20 to 40 grains—quinin in amounts of from 30 to 50 grains daily, veratrum viride in doses sufficient to bring and maintain the pulse below sixty, had the endorsement of many competent observers whose reports were certainly commendatory. The same may be said of venesection, which at one time was supposed to be the treatment *par excellence.* To-day the teaching is that the expectant plan with the meeting of indications by appropriate symptomatic remedies yields as good results as have heretofore been obtained; and there is much less probability of doing harm. Osler states in his 1899 edition that "Pneumonia is a self-limited disease which can neither be aborted nor cut short by any known means at our command. Even under the most unfavorable circumstances it may terminate abruptly and naturally without a dose of medicine having been administered. There is no specific treatment for pneumonia. The young practitioners may bear in mind that patients are more often damaged than helped by the promiscuous drugging which is still only too prevalent." The remedies advocated as specifics before the expectant plan was adopted were selected because of their antiplastic, antiphlogistic and antipyretic properties. Pneumonia was then supposed to be an inflammatory disease and was to be combated like any other inflammation. Calomel acquired its adherents because of its supposedly antiplastic effects, veratrum viride, on account of its antiphlogistic properties, and quinin because of its power over fever.

Flint made a long step in advance, when he announced his conviction that pneumonia was not simply an inflammatory disease of the lungs, but an essential infectious fever with pulmonic inflammatory manifestations. He it was who advocated large doses of quinin on this hypothesis. He writes, "As long ago as 1861 I was led, by the results of the analysis of a considerable number of cases in which sulphate of quinin was given to the extent of only 15 grains daily, to the conclusion that this remedy exerted a marked causative influence on the disease. I can now (1881) bear testimony to the fact that given in large doses, namely 20 to 30 grains daily, this remedy in a certain proportion of cases renders the disease abortive, and that when this does not follow, the disease is often modified to a greater degree than by smaller doses. Now, whatever efficacy belongs to the remedy proceeds evidently not from any direct effect upon the pulmonary affection, but from a controlling influence over the pyrexia, thus sustaining the doctrine that the disease is an essential fever."

---

[*] Read before the Nebraska State Medical Society, May 10, 1900.

The newer pathology of a pneumococcus infection was but a step in advance of Flint's doctrine, for it determined the actual cause of the infection. It holds that the disease is a general toxemia—resulting from the formation of toxins, produced by the development of the diplococcus in the lung, having a varying effect on the nervous system, the circulation, and the digestive tract, plus an inflammatory condition of the pulmonary vesicular walls and smaller bronchi, the direct irritative effect of the bacterial growth, which results in an exudate filling the air-vesicles and thus interfering with the functional pulmonary circulation and respiration by mechanical pressure. With what we believe now to be the true pathology of croupous pneumonia, may we not hope that a true specific will be found, or are we to calmly sit by the bedside and study the interesting clinical phenomena awaiting the crisis or a fatal termination with only symptomatic treatment? The true specific which shall be applicable to all cases must either inhibit the development of the pneumococcus in the lung—by directly destroying it or by rendering its environment inimical to its growth—or act as an antidote to the toxins produced. It must at the same time be innocuous. With these thoughts in mind I treated a severe case of embolic pneumonia of streptococcus origin nearly two years ago, by means of large doses of guaiacol carbonate, with good results, and was on this account deeply interested in a paper on "The Treatment of Pneumonia as Based Upon Recent Views as to Its Pathology," by Andrew H. Smith, of New York, and published in the *Medical News*, Dec. 6, 1899, in which he urges very strongly the use of guaiacol carbonate or the salicylates as a specific in this disease. He refers to Robinson and Kerr, who are recent enthusiastic advocates of the use of creosote both by the stomach and by inhalation. The great advantage of this remedy is that it can be taken in large doses without harm and that, being eliminated in part through the lungs, it has a double action. E. Congier in an inaugural address published in 1898, showed that the carbonate can be taken in very large doses up to a dram or more, without any irritation of the stomach, and that being slowly decomposed in the intestine, it liberates the creosote so that the blood is constantly charged with it even when there are six to twelve hour intervals between the doses. Thirteen cases from the clinic of Dr. Cassonte, of Marseilles, are reported in this paper, three of lobar and ten of catarrhal pneumonia, in which the carbonate was practically the only remedy employed. In every instance the effect upon the temperature was most marked, defervescence occurring promptly in the cases of lobar pneumonia, while in the catarrhal the severity and the duration of the attack were proportionately lessened. Dr. Wm. H. Thomson, of New York, in the discussion of Dr. Smith's paper before the New York Academy of Medicine, said, "Recently, in cases of double pneumonia, I have had excellent success with 20-grain doses of creosote carbonate administered every two hours. A very palatable emulsion can be made of the drug and patients take it readily. I have had three most unpromising double pneumonias recently recover under this treatment."

Robert Liegel, in 1898, reported seventy-two consecutive cases of recovery from pneumonia under the salicylate treatment. The patients were from 16 to 74 years of age. Eight had emphysema, six cardiac disease and a large proportion were alcoholics. The drug used was the sodium salicylate in large doses, not less than 120 grains daily. No other drug was used excepting an expectorant and small doses of morphin when pain was excessive. Under this treatment not only did recovery ensue in every case, but the duration of the attack was materially lessened and in no case did crisis occur, the temperature declining after the first day, reaching the normal by the fifth, when convalescence was established. The expectoration soon became catarrhal and the physical signs did not fully develop, or where they did rapidly retrogressed. In the first cases treated the remedy was suspended too soon, and a relapse occurred. After this was observed the drug was continued several days after convalescence, when no further tendency to relapse was manifested. Previous to the adoption of this treatment the management of the disease had been unsatisfactory and the mortality high. Liegel believes that the salicylate exerts a specific effect on the mucous membrane, increasing its secretion and throwing off the exudate. Dr. Smith believes that Liegel did not grasp the antibacterial idea of the action of the drug. He states that his own experience with this line of treatment has been encouraging, though not large. He has used all of the drugs which have appealed to him as specifics, with the exception of quinin, which has seemed too slow in action and too distressing to the stomach. He prefers the creosote carbonate to the salicylates, because of the gastric irritation often produced by the latter and its depressing effect upon the heart in the later stage of the disease. So enthusiastic is Dr. Smith in his belief of the efficacy of this plan of treating pneumonia that he urges the family physician "to provide his families with creosotal or one of the salicylates and to instruct them that with the slightest chilly sensation or the slightest stabbing pain in the lung, a dose is to be given at once, and that this dose is to be repeated at stated intervals until the physician arrives. This might prevent the development of pneumonia in some cases and shorten the attack in others."

Have we a specific for pneumonia in these two drugs, and by this I mean a remedy which will apply to all cases on antibacterial grounds, which will do no harm and which will not in any way interfere with the treatment of symptoms? This question I have attempted to solve to my own satisfaction during the past winter when I have had an opportunity to put it in practice, and I append a few illustrative cases, some of which were exceedingly severe.

CASE 1.—Mr. H., aged 35, single, accountant, had pneumonia several years before. When in apparent good health, he was seized with a shaking chill lasting one-half hour attended by severe pain under right nipple and a slight cough. Recalling his former experience he at once went to bed and I was summoned. On reaching him two hours later I found him with acute pain in the right side, temperature 101, pulse 96, respiration 24. During my visit he coughed and expectorated the typical rusty sputum. On physical examination there was diminished expansion of the right side, lessened pulmonary resonance in the lower right mammary region, and characteristic crepitant râles over a part of this area. He was given a prolonged hot bath, 5 grains of calomel, followed by a saline; a mustard and flax-seed poultice was applied to the chest and 15-gr. doses of salicylate of sodium were administered every two hours; and I enjoined absolute rest in bed after the bath, and liquid diet. In eighteen hours the pain was much less, he sweated freely, his temperature was 99.5, pulse 90, respiration 24, no further physical signs. Several times he had raised bloody sputum. Salicylate intervals were increased to three hours. In twenty-four hours later the temperature was normal, pulse 80, respiration 20, sputum only slightly tinged. From this time he went on to complete convalescence, the salicylate being kept up for five days more at longer intervals.

Case 2.—Miss E., aged 30, single, teacher, three days before my first visit had a severe chill while at work, followed by lancinating pain in the right side, and dry hacking cough with fever, severe nausea and vomiting, the latter occurring several times. On first examination her countenance was flushed and expression anxious; there was severe pain in the right nipple line through the shoulder; her tongue was much furred, and she was exceedingly nervous and sleepless; her temperature was 104 F., pulse 100, respiration 40; the cough was dry and painful, and no sputum had been raised. Physical examination showed much-diminished expansion on the right side, increased vocal fremitus, complete dulness and bronchial respiration with bronchophony over right infrascapular and axillary regions. The treatment consisted in liquid diet, absolute recumbency, calomel 8 grs., followed by a saline; guaiacol carbonate 8 grs., strychnia 1/40 gr. every two hours; codein 1/2 gr. and phenacetin 4 grs. for the pain; mustard and flax-seed poultice covered by oiled muslin.

Fourth day.—The patient's temperature was 104, pulse 108, respiration 52; she was delirious most of the time, and her sputum was rusty. Consolidation of the right lung extended to the mammary region, and there were signs of consolidation in left infrascapular region; the treatment was continued.

Fifth day.—The temperature was 104.2, pulse 108, respiration 50; there were delirium, labored breathing and marked cyanosis; oxygen gas was administered for twenty-minute periods every alternate hour.

Sixth Day.—The temperature was 101.4, pulse 106, and respiration 38.

Seventh day.—The temperature fell from 101.4 to 99.6, the pulse from 106 to 92, the respiration was 40.

The termination was by lysis, and convalescence was uninterrupted. The total amount of guaiacol carbonate given in four days was 320 grains.

Case 3.—Mr. N., single, aged 28, chemist, previously well, was seized with severe chill, followed by fever, and pain in the right mammary region. I saw him first on the third day, when his temperature was 104, pulse 120, and respiration 40. He had a cough and expectorated the typical rusty sputum; there was slight delirium and his tongue was thickly furred. The physical signs gave evidence of complete consolidation of the upper lobe of the right lung. The treatment was: calomel 8 grs. followed by a saline; guaiacol carbonate 8 grs., and strychnia 1/30 gr. every two hours; absolute recumbency; liquid diet.

Fourth day.—The temperature was 104.5, pulse 120, respiration 50; the delirium was most pronounced, and there was much restlessness; the tongue was brown and dry, and the consolidation extended to the lower lobe, also to the lower lobe of the left lung. The guaiacol was increased to 12 grs.

Fifth day.—The temperature was 105, pulse 140, respiration 60; there was muttering delirium, sordes tended to collect on the teeth, and cyanosis was commencing. The right lung was completely solidified, the left lobe showed an increased amount of solidification, the heart sounds were feeble but regular. Oxygen gas treatment was commenced, twenty minutes every alternate hour; strychnia was increased to 1/20 gr. hypodermically every two hours; 8 grs. calomel were followed by a saline.

Sixth day.—The temperature was 103, the pulse 103, and the respiration 50; the delirium was less marked; there was restlessness, but cyanosis was not continuous, the tongue was moist, and there was commencing resolution in the upper right lung. Oxygen gas gave great relief, but the patient wanted it no longer than ten minutes; the treatment was continued.

Seventh day.—The temperature was 101, the pulse 108, and the respiration 50; there was no delirium, and the physical signs of resolution in right lung were extended and were commencing in left.

Eighth day.—The temperature was 99, the pulse 100, and the respiration 40. From now on convalescence was uninterrupted and resolution became complete in three or four days. Guaiacol was continued for one week in lessened doses, as was also strychnia.

Case 4.—Mrs. M., aged 32, for several years in delicate health, had a chill with fever and severe pain in right axillary region, and a cough with mucopurulent expectoration. Physical signs of consolidation were not manifest until the sixth day, when they were found in the lower lobe of the right lung; her temperature was 103.4, and her pulse 90. Guaiacol carbonate 12 grs., and strychnia 1/30 gr., were administered every two hours. From this time on for six days the temperature ranged from 101.9 to 104.4, the highest pulse was 120, the highest respiration 60; delirium was marked at times. Resolution took place by lysis, but the temperature did not reach the normal. After one week of improvement the temperature and pulse increased, when physical signs of a pleural effusion were found. An exploratory paracentesis thoracis revealed pus in the infrascapular region after two failure punctures in the mammary and axillary regions. A pleurotomy with rib resection was performed by Dr. Jonas, which was followed by a tardy though continued convalescence, with complete expansion of the lung.

Case 5.—Mr. H., aged 45, married, clerk, very robust, had a cold and cough for several days while traveling. A chill followed by fever and pain in right side occurred before reaching home, and two days before my first visit. I found the temperature 103, the pulse 110, and the respiration 36; the cough was accompanied by an expectoration, prune-juice in character. There were physical signs of general bronchitis, and consolidation in the right infrascapular region. Guaiacol carbonate 10 grs. and strychnia 1/20 gr. were commenced at once, and 6 grs. calomel were given, followed by a saline. Under this treatment and a mild expectorant, resolution took place by lysis so that by the sixth day the temperature was normal, and the bronchitis slowly disappeared.

Case 6.—Mr. C., aged 50, married, accountant, was seen in consultation on the fifth day after a severe chill, followed by high fever and some pain in the side. His temperature had ranged to upward of 104 and pulse to 115. At my first visit he was partially comatose, the tongue was brown and dry, and there were sordes on the teeth; there was enormous distension of the abdomen from gas, and complete consolidation of the right lung. I prescribed calomel 6 grs., to be followed by a saline; sodium salicylate 15 grs. every two hours for four doses, then at longer intervals, and strychnia 1/20 gr. The following morning the temperature had dropped to about 102, and the pulse to 112; the abdominal distension was relieved, the tongue was moist, but the stupor had increased and cyanosis was manifest. Oxygen gas was commenced in the afternoon. The same evening the pulse was 124, and the temperature 103; there was incontinence of feces, the coma had increased, but commencing resolution was manifest in the consolidated lung. In spite of large doses of strychnia and digitalis, hypodermically, the patient died comatose the same night.

Case 7.—Mrs. S., aged 38, housewife, of rather delicate constitution, had been curetted by me on the eighth day after labor, for a sapremia of mild type which had not yielded to uterine irrigation. Her temperature was practically normal and her condition very favorable until the fifth day following, when she had a chill, with headache and general malaise, followed by a temperature of 103.5. The next day severe pain developed in the left inframammary region, which required morphin hypodermically for its relief. A careful physical examination made after the pain was controlled, when the respiratory movements were free, was negative. Fearing the development of pneumonia, at my next visit I took with me 5-gr. capsules of guaiacol carbonate.

Third day.—The temperature was 103, pulse 128, respiration 49; the pain returned and was also present in the supraclavicular region. There was no cough. Physical examination showed consolidation in the left infrascapular region, crepitant râles distinct in inframammary region of the same side. I ordered guaiacol carbonate 10 grs., strychnia 1/20 gr. every two hours, and codein as required for the pain.

Fourth day.—The temperature was 103.2, the pulse 140 and irregular, the respiration 38; perspiration was free and tympanitis marked. Vaginal examination, abdominal examination negative and physical signs the same, but crepitant râles in addition were heard in the supraclavicular left and inframammary right, but there was no cough.

Fifth day.—Morning temperature was 102, the pulse 140, the respiration 44; at 5:30 p.m. she had a chilly sensation for a half hour with a temperature of 106 following, the pulse was not countable, the respiration 40; at 10 p.m. the temperature was 104, pulse 148, respiration 36.

Sixth day.—The temperature was 101.4, the pulse 136, and the respiration 24. Signs of resolution were marked over the consolidated area, and no extension where crepitant râles were heard elsewhere. For the first time she expectorated a bloody sputum which on bacteriologic examination by Dr. Lavender was found to contain staphyloccoci, pneumococci and a very few streptococci. During the next few days all evidence of pulmonary trouble disappeared and the temperature, pulse and respiration became normal. The guaiacol was continued in the same dose at longer intervals.

CASE 8.—This was a case of embolic pneumonia, the result of a septicemia from a self-induced abortion at the second month, terminating in abscess and the expectoration of large quantities of pus containing streptococci and staphylococci. The pulmonary infection occurred in the left mammary region and gave the typical signs of consolidation, with temperature ranging from 102 to 104 and pulse 130. Large doses of guaiacol carbonate with strychnia was the only medicinal treatment, the patient convalescing in ten days with good results.

This case can not be classified with the ordinary pneumonia of pneumococcus origin, and is recalled because of the apparent influence of the antimicrobic treatment over a septic embolic pneumonia.

Individual statistics bearing upon the treatment of disease carry weight only with him who has been through the personal experience of the foundation for the statistics. It requires a collective investigation to determine whether in reality any progress has been made, and more particularly is this true of pneumonia, a disease which is attended by so many surprises, and the results of which are so uncertain. My own experience with the remedies which are so earnestly advocated by Dr. Smith is so limited that I hesitated to bring the subject before you at this time; yet I was so impressed with the results in some of them, which represent the severe types of double pneumonia that I desired to suggest a trial along the same line, in order that we might the sooner ascertain whether we yet had a specific treatment for this disease. We must go on hoping that we shall accomplish as much in this direction as we have in the treatment of malaria, of syphilis and of diphtheria. It is all well enough to write and talk of treating the individual instead of the disease but when we can do both with the same degree of intelligence, we shall lower the mortality of pneumonia to figures which, to say the least, will not be alarming. So far as we know I would rely upon the guaiacol or salicylates as specifics in pneumonia, giving preference to the former in cases past the stage of congestion, in the enfeebled, or where there were heart lesions. The addition of strychnia to the salicylate treatment obviates in part the depressant effect upon the heart, and so does alcohol. I combine strychnia with the guaiacol also for its influence upon the nervous system, and to prepare the patient for very large doses, if they become necessary. I shall not take up your time with the details of the individual or symptomatic treatment, except to say that I have found the hot poultices more agreeable than cold; that I would resort to venesection when there was an overloaded right heart with threatening symptoms; that digitalis is reserved for an irregular and flagging heart; codein in small doses for the relief of pain and delirium; strychnia in increasing doses and alcohol for enfeebled heart action; calomel and saline for constipation or sluggish portal circulation; that oxygen gas is commenced at the first sign of cyanosis and in quantity sufficient to relieve; and last, but by all means first, the absolute recumbent posture until resolution is established.

APPENDICULAR FISTULA.[*]

JOHN B. DEAVER, M.D.
PHYSICIAN-IN-CHIEF TO THE GERMAN HOSPITAL.
PHILADELPHIA.

The subject of my remarks to-day, appendicular fistula, is such a common sequel to operations for acute appendicitis and is of such great importance to the future welfare of the patient, that I can not too strongly invite your attention to this subject. It is one of the most important sequels to appendicitis operations, for several reasons: on account of its effect on the constitution, the organs it may involve, and the danger in which it may place the patient in regard to future health. That many fistulæ may be avoided, if earlier operative measures were instituted, can not be questioned. This apparently is a very strong presentation to make, but I shall endeavor to show later in the discussion my reasons for making such a statement. I shall discuss this subject by taking up the varieties, the causes and dangers, the means of prevention, and the treatment.

There are two types of fistulæ of appendicular origin—the external and the internal. The external is subdivided into two, the simple and the fecal. The simple fistula is also of two kinds; the first is where the external channel leads from an unhealed abscess cavity and corresponds to the site of the drainage tract. This variety is simply a suppurating sinus, and tends to heal spontaneously. The delay in healing may be due to the presence of an infected ligature or a piece of gauze used for drainage purposes, and which has dropped into the wound and been lost. On the escape of the ligature or the removal of the gauze, closure of the fistula takes place. In the second variety of simple fistula, the lumen of the appendix is in direct communication with, and discharges its contents into, the fistula. The material which is discharged from the fistula is clear mucus. This variety is found when the lumen of the distal portion of the appendix is in direct communication with the fistula, the lumen of the appendix has however become obliterated at some point, or the organ has, from the inflammatory process, become separated from the cecum or in its continuity, thus allowing the secretions of the organ to escape through the fistula.

There are two varieties of the fecal fistula consequent on appendicitis: 1. Those in which the lumen of the approximal portion of the appendix is in direct communication with the fistula, and from which there is a fecal discharge; this discharge later becomes entirely mucus or but slightly stained with fecal matter. 2. Those in which the cecum, the ascending colon, the small intestines, or both small and large intestines, are in communication with the fistula; the opening into the bowel may be so extensive that it may practically amount to an artificial anus.

---

[*] Presented to the Section on Surgery and Anatomy, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

The factors in the production of appendicitis are likewise the cause of fistula. The invasion and the destructive activity of micro-organisms is in a large measure responsible for this condition of affairs. It is responsible for the softening and gangrene of the appendix and the adjacent bowel. Necrosis from pressure occasionally occurs. Pus is not an essential factor in the production of a fistula, although abscess is undoubtedly the exciting cause in the majority of instances, from the pressure which is attended with necrosis. The pressure of a drainage-tube or the cutting out of sutures which have been introduced into a bowel wall already weakened from the inflammatory process are also causes of fistulæ.

The source of the fecal discharge will be found to be from an opening into the bowel, or from an appendix which has separated from the bowel and discharged the bowel contents from its proximal end or from both.

The persistence of a fecal fistula may be caused by the continued use of a drainage-tube. I have seen a number of cases which were rapidly cured after discarding the drainage. One in particular demonstrates this point: The patient, a youth, was twice operated on for appendicitis with a fistula having two outlets, one on the right side, discharging bile and feces, and a second on the left side, from which pus made its escape. I found in this case that a large-sized drainage-tube had been introduced into the pelvis and had been worn for a number of weeks, without any diminution in the amount of the discharge. The drainage was removed at my suggestion, and this was followed by prompt closure of the fistula.

A fistula does not always make its appearance early, i. e., within a few days after operation; it may not make its appearance for a week or ten days, and one should not dismiss the possibility of this complication occurring even at some more remote period. The following case will show the possibility of a late development of fistula: The patient, a young woman, was operated on for an appendicular abscess. The appendix was not removed at this time, for two reasons—on account of the softened condition of the bowel forming the wall of the abscess cavity and because the appendix was very deeply situated, it was feared that the bowel might be torn in the necessary manipulation to free the appendix. The appendix was therefore left for a subsequent operation. The abscess cavity was packed and allowed to heal by granulation. After ten days had elapsed the dressings were found to be bile-stained, and also with fecal matter. The fistula showed no prospect of a spontaneous closure and later developed an exceedingly painful eczema about the external opening of the fistula. The usual dressings for the eczema had no effect whatever, and the patient's condition became so bad that operation for the cure of the fistula became imperative. Before operation was resorted to all food by the mouth was suspended and nutritious enemata given, but these excited so much rectal tenesmus that they had to be discontinued.

The operation was attended by a number of difficulties. There was a mass of adhesions covering a large area and binding the large and small intestines down to the region of the gall-bladder, calling for extensive and careful dissection to properly expose the fistulous communication with the bowel. The fistula was found to involve the duodenum, as was anticipated, and called for excision of a portion of the bowel, and anastomosis. The unhealed abscess cavity was found unhealthy in appearance and covered with a dirty grayish granulating surface. The lining of the cavity was stimulated and repacked with iodoform gauze, and the abdominal wound closed, except at the point of exit of the packing. A period of two weeks elapsed, when the patient again complained of pain in the region of the wound. The dressings were removed and it was found that the fistula had recurred, and to a more serious degree. The discharges from it were fluid and would contain milk that had been swallowed but a few moments before. Pure bile also escaped from it. Owing to the nature of the fistula, the recurrence of the eczema and the rapid emaciation of the patient, another operation was done. On opening the abdomen and exposing the duodenum the line of the previous operation was seen and found to be intact. The opening in the duodenum was found some distance from the site of the former operation. The duodenum was greatly dilated and thinned out, the opening being large enough to permit the escape of the entire bowel contents, and it was necessary to excise at least five inches of the duodenum in order to include healthy tissue in the anatomosis. An end-to-end enastomosis was performed, the thinned portion of the bowel reinforced by peritoneal flaps, and the external wound closed after packing had been introduced into the unhealed abscess cavity.

The character of the discharge in the external variety of fistula varies according to the type of the fistula and the stage at which it is seen. If seen early, the discharge is fecal in character, except in the type where it proceeds from a separated appendix which is not in communication with the bowel. If the appendix is not removed at the time that the abscesss is evacuated and a fistula supervenes, then the appendix will be found to communicate with the fistula. In one case the appendix was noted to be separated at the time of the evacuation of the abscess. A fecal fistula which had a very small external opening—one not large enough to permit the passing of a probe—resulted. This fistula was treated expectantly, in the hope that it would close spontaneously, but it persisted, and an operation for its closure revealed the appendix to be in communication with the fistula, separated from the bowel and attached to the abdominal wall, draining through the fistula. Recovery followed the removal of the appendix.

A patient with appendicitis, who was originally treated for a perinephritic abscess, which was opened and drained, complained of pain in the region of the loin, and right iliac region, three or four weeks after the wound had healed. The patient was admitted to the German Hospital. On placing him on the operating-table, under an anesthetic, a strong fecal odor was detected, as though he had defecated. On exposing the wound from the former operation, a free discharge of fecal matter was found; it escaped from an opening in the cicatrix, which had broken down at this point. The part was carefully cleansed and an aseptic pad placed over the opening. The patient was placed on his back, an incision made through the abdominal walls over the appendix, and the latter exposed, which was found occupying a post-cecal position and in direct communication with the fistula, the contents of the cecum making its escape through the appendix and out into the fistula. The appendix was removed, the abdominal wound closed, drainage introduced into the former fistulous tract. Recovery followed.

The internal variety of fistula occurs as the result of the evacuation of an abscess into one of the hollow viscera, and is believed by many to be a most favorable termination to pus formation. To this view I must make very strong objections, for I have seen too many cases where this has occurred and been followed by distressing consequences. In one case there was a fistulous communication with the bladder, which ultimately cost the patient his life; in another the fistulous communication was between the appendix and the dilated portion of the ureter, which permitted the escape of feces through the ureter into the bladder and then to the exterior. In still another the fistula was in communication with the upper air-passages. The most favorable variety of internal fistula and that in which the patient incurs the least risk to life is where the abscess breaks into the cecum or the ascending colon. Where the abscess breaks into an adjacent coil of bowel it has, in a number of instances, been the direct cause of an acute internal intestinal obstruction, and caused loss of life therefrom. Acute intestinal obstruction is caused by the slipping of a knuckle of bowel under the point of adhesion of the fistula.

The constitutional effect of a fecal fistula is evidenced by a more or less rapid loss of strength and impairment of nutrition, due to the loss of the bowel contents containing the elements necessary for nutrition. This is more especially true when the fistula occurs high up in the small intestines, either in the duodenum or the jejunum.

As I have before stated, there are several factors which are the exciting causes of appendicular fistula: abscess formation; migration of micro-organisms into the bowel wall, causing softening; separation of the appendix from the bowel; the introduction of too many sutures or tying the sutures too tight in a softened bowel; the presence of the drainage-tube, and pressure necrosis.

On referring to all these causes we can see how easy it would be to prevent the occurrence of any and all of them by instituting surgical interference directly after the onset of an attack of appendicitis. If the appendix is removed immediately after the attack occurs, i. e., before any serious involvement or impairment in the nutrition of the contents of the right iliac fossa takes place, then it is impossible for abscess to occur, except from some fault in the technique of the asepsis; and it will be impossible to have softening of the bowel and cutting out of the sutures, the introduction of drainage will be dispensed with, the likelihood of adhesions lessened and any of the sequelæ which almost always follow neglect in having the patients operated on at the time of election—at the commencement of an attack—be avoided.

The treatment of appendicular fistulæ of the external variety varies with the individual cases. It is well, however, to permit Nature to attempt a cure. The surgeon's attention should be directed to maintaining thorough cleanliness and to regulating the diet. Frequently a fistulous tract will heal spontaneously if the diet be solid food and the bowel contents be kept rather hard. It is not wise to use a syringe, as it irritates the tract. If the fistula persists after the lapse of a reasonable time, operation offers the only hope of cure.

The operative treatment of the simple fistula should consist in exploring the tract to ascertain whether an infected suture be the cause. If it is, this should be removed and the tract curetted and packed with gauze. This usually suffices to insure a cure. When the fistula or sinus communicates with an unhealed abscess cavity, the mouth of the fistula should be enlarged sufficiently to permit of thorough cleansing and packing. When possible without opening the peritoneal cavity, the mouth of the fistula should be enlarged to a degree to equal the transverse diameter of the abscess cavity at its widest part. This should be followed by thorough cleanliness, packing, etc.

The treatment of fecal fistula necessitates opening the peritoneal cavity, removing the appendix—or its remaining portion, as the case may be—and thoroughly breaking up all peritoneal adhesions. When the fistula is in communication with one or more openings in the intestine, closure, preferably by suture, is to be recommended, but resection, end-to-end union, etc., is frequntly required.

To summarize the points which I desire to make: 1. The fistula is one of the most important sequels of operation for appendicitis. 2. Certain cases of fistula tend to close spontaneously. 3. When the fistula causes marked constitutional effects, delay in operating is a menace to life. 4. It is possible to avoid fistulæ in the great majority of instances if operation is instituted early. 5. Operative cases of fistula are usually curable, rarely requiring a repetition of the operation for its correction. 6. The fistula does not necessarily occur directly after the operation for the removal of the appendix or the evacuation of an appendiceal abscess.

1634 Walnut Street.

EDUCATIONAL AND LEGISLATIVE CONTROL OF TUBERCULOSIS.*

CHAS. DENISON, A.M., M.D.

DENVER, COLO.

The idea that a known (?) disease like tuberculosis springs from the evolution or rather dissolution of the forces which have to do with our being, that it is an evidence of the variation of the law of harmony to environment, a retrograde movement toward dissolution and death; this idea, I say, of a basic law of degeneracy, which finds its chief expression in this wasting disease, is too profound to be easily grasped, too adverse to our set habits of thought to be easily accepted. Therefore, if I fail to convince the reader in a necessarily curtailed presentation of proof, let me suggest that he simply suspend judgment till the opportunity happily occurs for him to study John Fiske's "Outlines of Cosmic Philosophy," especially the interesting chapters on "Matter, Motion and Force;" "Rhythm;" "Evolution and Dissolution" and "Sources of Terrestrial Energy." Then, I think, he will come to the conclusions here reached and have a clearer understanding of the matter.

There is a deeper and more fundamental source of knowledge than that which the microscope with its wonderful delineation and detail can supply, and the liability of being side-tracked by that instrument's findings should be recognized, that we may not fail to grasp the true origin and evolution of our degenerative diseases.

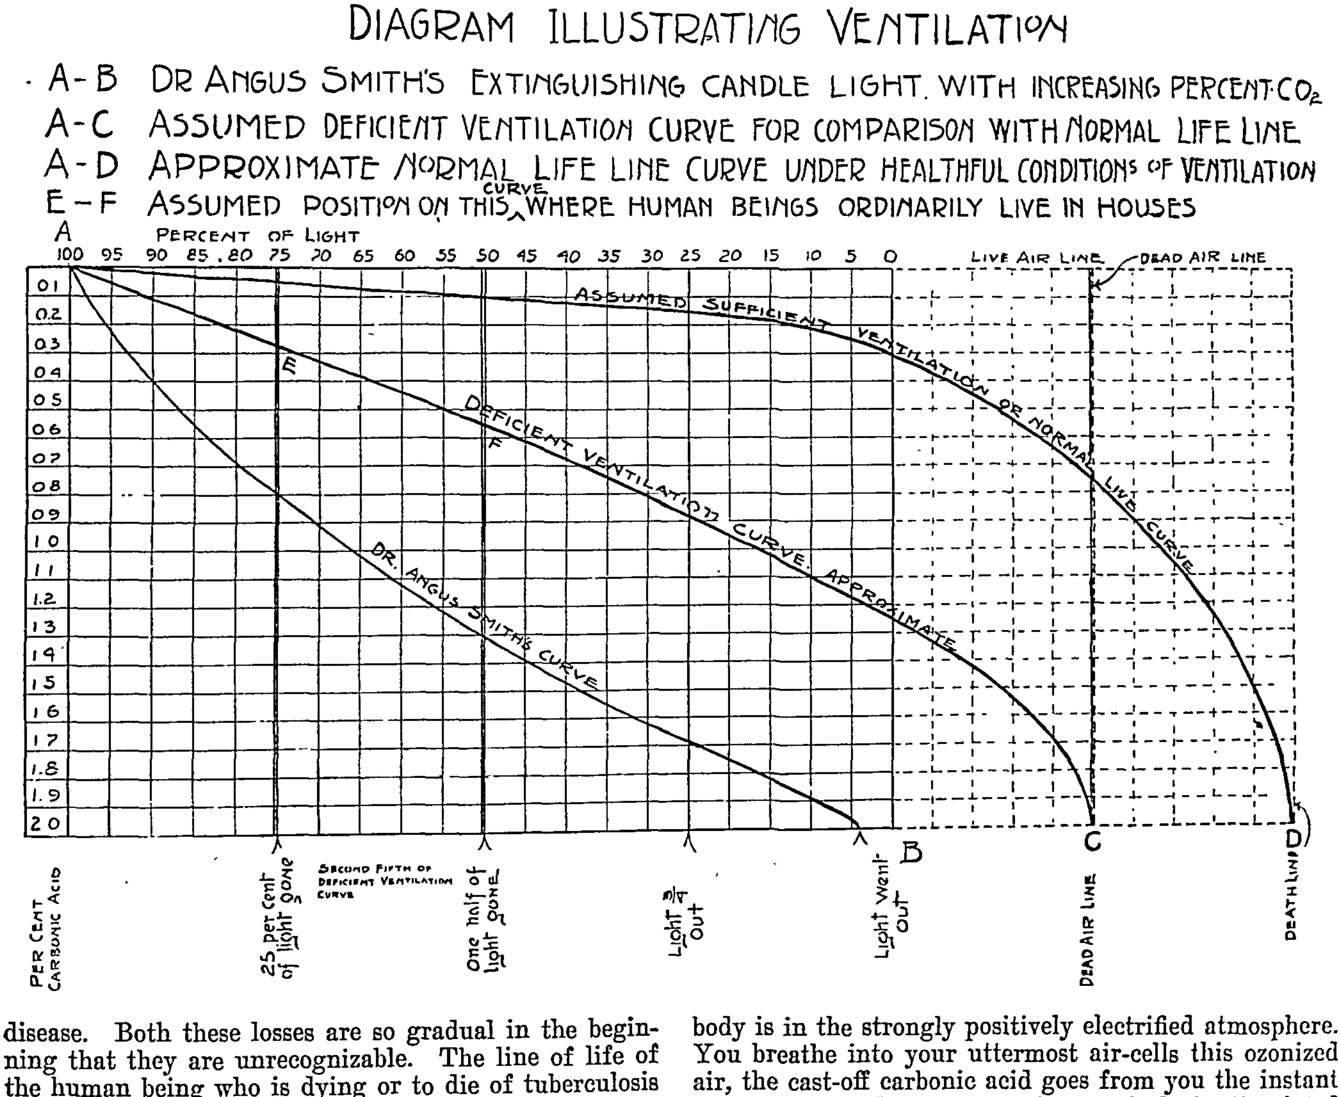
An important fact in evolution is that, all the way up to man, the beings evolved have had no voice, save instinct, in deciding their destiny. With the advent of man, however, something was added to the law of the survival of the fittest, that is, a deciding brain. This

---

*Read before the American Climatological Association, Washington, D. C., May, 1900.

at right angles thereto, then the gradations from live air to dead, under the subtle influences in which we human beings live and die, can be truthfully represented as a curved line which gradually leaves the horizontal line and comes down to the perpedicular. This deficient-ventilation curve is not the same, but is much like Angus Smith's curved line (see illustration) which indicates, at times, the measure of the light of a candle when gradually extinguished by being confined in a closed space.

This receding flame can be fanned into life by opening a window, but let the previous stillness continue and the perpendicular line of extinguishment is surely reached. I wish to call attention to the important fact of the *proportionate and gradual loss of light, and by it to illustrate* the proportionate loss of vitality in a degenerative disease. Both these losses are so gradual in the beginning that they are unrecognizable. The line of life of the human being who is dying or to die of tuberculosis has a similar curve. So gradual and imperceptible to his comprehension are its graduations that he does not know where he is on the bend of the curve, but he knows quite as much about it as he does about the deficient-ventilation curve, represented by *the graded line from live to* dead air. We do not apreciate our individual positions on this ventilation curve, as to the respective confinements of our bodies in closed spaces and the resultant imprisonment and dwarfing of our respiratory and circulatory systems; and it becomes a pertinent question to each one of us: Will we be exterminated by these conditions or will the final extinguishing act be transferred to our children, handicapped as they will be by our present ignorance?



Where on our imaginary deficient-ventilation curve, is the room we have described? Do I controvert the judgments of physicians who have so often felt like smashing the scanty windows of the sick-room or sleeping-chamber in order to let in some pure air, by saying that its imperfect ventilation places it 20 to 40 per cent. along on the downward extension of the curve? Admitting this you see the whole force of my argument. We must judge by contrast, and our sensations are only partial guides. The purest air, and therefore the liveliest air I know of,is found when you stand on some eminence in the rays of the rising sun, with the air coming to you from the hills or mountains beyond, sifted through pines and firs; *with your feet upon the dry but negatively electrified* ground, while your head or perhaps your whole body is in the strongly positively electrified atmosphere. You breathe into your uttermost air-cells this ozonized air, the cast-off carbonic acid goes from you the instant it is exhaled and every nerve in your body is stimulated to normal life.

The deadest air, I think I ever breathed was in the mammoth cave of Kentucky. I found there little 12 by *6 by 8 ft. rooms constructed of stone,with one door and* a 16-inch square window in each. They had been built for the supposed climatic effect of the equable temperature, always 58 F. I was told that they took sixteen consumptives down there for one month. Four died there, one a week after coming out, and none were benefited. In comparison with the positive effects of live air cited above, such negative conditions, such deadness of atmosphere and ignorance of the requirements of human beings give the mind an ineffaceable shock.

Should a further illustration of dead air be needed, let us consider the lead chamber which Angus Smith constructed for his experiments[3], in which no possible interchange of air with that outside could occur. Imagine Dr. Angus Smith remaining therein, rebreathing its atmosphere as he did till candles went out, and you will have a good idea of what I mean by absolutely dead air, the effects of which, as described by this faithful investigator, I have no time here to dwell upon[4].

Previous to this experiment, Dr. Angus Smith had thought the real evil was from organic substances in the air, but afterward he concluded that carbonic acid, even in small amounts, had an injurious influence. In this connection it is interesting to note that Lavoisier and Saguin found that the human limit of the possible rebreathing of air was when the carbonic acid had reached 10 per cent. and that "was bearable only for a short time," while Angus Smith says "it seems to be impossible to endure 4 per cent. for any length of time."

The life of the air consists, to a greater extent than has been heretofore recognized, in the molecular motions of its atoms caused by the sun's influence. The diffusibility of the air, the easy motions due to changes of temperature in different strata, and the fact that light and sound depend upon the wave-motions of ether, are all forms of molecular activity which probably impart the life-giving principle to our atmosphere. This motion is always present till meddlesome man interferes. For instance if a narrow beam of light is thrown into a closed dark room in which the air is apparently still, every particle of dust is seen to be in constant motion. From the fact that there are varying states and amounts of electricity in the different strata of the atmosphere, the conclusion is justified that finer forces govern the life of the atmosphere than merely its composition of oxygen, nitrogen, moisture and carbonic acid. Nor should we forget the contribution of vitality vegetation brings through its constant interchange of oxygen for carbonic acid. This, with the qualities of atmospheric electricity and molecular motion, is all in restraint if not annihilated in poorly ventilated rooms.

This restraint of molecular motion and consequent limitation of vitality are in direct proportion to the deficiency of ventilation. Herein I conceive lies the great mistake of our civilization in relation to healthful human life. Here is to be seen the need of education that this cause of disease may be understood.

Let us try to elicit analagous evidence of vitality in the growing media of other products of Nature than those of the dwellers above the surface of the earth. The ground in our latitude becomes dead earth to vegetable growth as the cold of the Fall and Winter gradually annuls its vitality; but the warm penetrating rays of the sun in Spring and Summer transform it into live earth for the wonderful fructification of plant and animal growth. Plants too have their life-curve, which depends upon the vivifying and transmitted influence of the sun's rays. Shut out that influence and the life-curve becomes immediately abbreviated.

Again, let us consider the fish class, a medium creation depending upon air and water for its atmosphere and food. They constitute its life-giving agency and can not be greatly changed without its extinction. How wonderful is the effect of the fish's environment upon its life-curve, and upon its distinguishing characteristics, as shown by the eyeless inhabitants of dark caves, the big-eyed sunfish of the open pond, the sluggish sucker of the mud creek and the lively grayling of the rapids.

The livest water I have ever seen was when, within view of a snowbank in the Rocky Mountains, a cold dashing stream lashed itself, by its perpetual motion over rocks and stones, into a fit abode for the mountain trout, that creature full of ozone and vim, which life elements he transmits even to the fisherman who joyously captures him.

Note the difference in the life quality of that trout and of another of the same species pulled sluggishly up from 100 feet below the surface of a still lake. The higher the order of evolution, i. e., the more delicate and special the development of the nervous structure, the more susceptible to and influenced by the changes in environment are all created beings.

Applying this principle to the human family, we see that a limit of civilization can be reached where delicate or slight changes of environment may cause dissolution as well as evolution; where extinction from lack of conformity may take the place of evolution because of conformity to our environment.

We may argue against the cramped chest and round shoulders of the bicycle rider; but the bicycle is doing a world of good in getting people out of doors, in addition to the improved aeration of the blood which results from its use.

We admit the "visiting the iniquities of the fathers upon the children unto the third and fourth generation," meaning, in these days, syphilis and like hereditary evils; but this law of transmission likewise works itself out to the extinction of the users of defective and deficient ventilation.

We discuss the inhalation of irritant powders and poisonous gases in certain hazardous occupations; but defective ventilation, considered in conjunction with such causes of disease, increase their injurious effects manifold.

We may reason that the tubercle bacillus being the constant accompaniment of the decaying process in tuberculosis is consequently the cause and source of all this evil; but the very lateness of its appearance shows it to be rather the result than the cause. Its absence in many forms of scrofula, adenoid growth, wastings and catarrhs which surely eventuate in mature tuberculosis show that the pre-tubercular stage and perhaps the first stage of tuberculosis are already established presumably in advance of the germ. These conditions have been proved by the tuberculin test to be a part of the real disease before the microscopic or any other ocular demonstration of the bacillus is possible. The Widal test for typhoid fever now joins the tuberculin test in showing a dyscrasia which we know to be due to the presence of latent tuberculosis. This occurs before any ocular evidence of the mature germ is possible.

The destructive influence of sunlight upon the tubercle bacillus is now generally admitted[5]. If, in addition, the contention of Frankel,[6] that it is a facultative anaerobic germ, is sustained, then the claim of a predisposing cause in defective ventilation is strengthened by the favorable conditions furnished for such germination in the unventilated lung.

We thus go back of the tubercle germ to conditions which are bound, under favoring circumstances, to eventuate in it, and the following important statement is warranted, which controverts the trend of scientific thought of this decade as to the prevention of tuberculosis—namely: If all of Koch's bacilli of tubercle on this earth were instantly destroyed, in due time, under the same conditions, our world would again have an ample supply. It is not for me to pretend to know the exact time which would elapse, under such a supposed temporary dispensation of Providence, until the terrible intensity of the "white plague" would be again as great as at the present time. The old times would come back soon enough. Undoubtedly, some of us, even those who are now incubating the germs, would live longer and be much wiser for such experience. We would, however, surely see the wave of bacillary domination sweep back over the human race, bringing the equivalent of the present time, when, as Osler says, 2 per cent. of the people living have the disease, and when, as it seems to me, ten times as many are getting ready for it.

Tuberculosis has come here to stay until we, the thinking masters of creation, acquire the education to understand and abolish it. It will not "down" in response to any edict against street expectoration, the disinfection of rooms occupied by dying consumptives, or even the slaughtering of tuberculous cows, although these measures of prevention are most important.

The drift of this reasoning is to this conclusion: Tuberculosis springs from, or is the outgrowth of, some unified cause which will account for its existence in cattle and horses, birds and other animals, as well as in man.

I wish to refer to the excellent paper presented by Dr. Charles Gresswell to the National Live Stock Association at its late meeting in Fort Worth, Texas.[7] From his considerable experience as a veterinarian in Colorado he shows that it is entirely unnecessary to use the tuberculin test with the "plains" cattle in the Rocky Mountain region, because even those previously infected, and transferred to the plains, there outlive their tuberculosis, and it does not appear in the next generation. In proof, he instances the surviving members and the progeny of a very badly infected herd of overbred Shorthorns, inbred and closely housed, of which I myself was cognizant. If also you bear in mind the great mortality from phthisis, etc., of the French and English cavalry horses under close stabling, which was quickly prevented by open-air stabling[8]; if also you are acquainted with the corroborative evidence of the close domiciling of cows, the confined caging of birds, monkeys, guinea-pigs and other animals, the crowding[9] of human beings in ship-holds, prisons,[10] alms-houses,[11] and places of public detention, or the civilizing and housing of savages, as of the American Indian, you then have to come to the conclusion that tuberculosis results either from a species of autoinfection from rebreathing the body's own exhalations, or from the fact that the air of these confined spaces becomes a source of infection from the loss or annulment of its life-giving principle.

Thus we are brought back to our sample room, the abode of a human being, the meagre size of which, and its deficient sunlight and air circulation, afford a sufficiently marked degree of deficient ventilation to constitute it a glaring fault of our civilization. This now seems to be the initial cause or starting-point of tuberculosis, which probably kills more people than war together with any other one form of disease known.

The study of the remarkable diffusibility and penetrability of gases, even through glass windows and brick walls, not to mention wooden doors with the many cracks around them, gives us some hope through what is called "insensible ventilation."[12] But the fear is that even this much of protection will be annihilated through the perfection of carpentry. The education which the people need, even the common people, and we doctors too, *must* be obtained and the architects and builders are not exempt from this necessity.[13]

A more thorough study of this intricate question would lead the architect, whose usefulness is too much limited by the demands of an ignorant public, to be an upbbuilder of people's health as well as of their houses. It is to be hoped that he will thus arrive at a more encouraging conclusion than did James A. Greenlief, C. E., in his "How Much Ventilation?" when he said "For the ordinary private house a systematic air allowance per individual is almost an absurdity—for many of them a thorough systematic plan of ventilation is unnecessary, even were it not debarred by reason of the expense inseparable from it."

Whether ventilation, suited to the size and purpose of a building, the climate and the exposure, shall be by natural or artificial means, whether by propulsion or extraction, and how it shall be modified by the artificial aid of heat, steam and electricity, I have not time to consider in detail. My object now is to emphasize the need of ventilation of our living and working rooms. Lack of ventilation leads to the pale face, sallow skin, weak pulse, cold hands and feet and sluggish bowels; the feeble powers of digestion, assimilation and nerve energy—all proofs of a flagging vitality. This lethargy is due to enfeebled and poisoned blood-corpuscles, and a probable autoinfection, but especially to deprivation of food for the blood, i. e., oxygen from the air. In addition, the dead air, which marked deficiency of ventilation implies, compels inactivity and limited use of the lungs, and this, in turn means the gradual clogging of out-of-the-way air-cells with the products of combustion. In this manner, carbonic-acid poisoning and the species of autoinfection, heretofore described, are most naturally located and more or less permanently establshed.

I will not pretend to say what the details of a law of ventilation should be, but there should be such a law, enforced by proper legislation. That detail will be an outgrowth of the education which is essential to right legislation. In general, however, it should determine the minimum ventilation allowable in every assembling-place or habitation for human beings, and for dairy cows, horses, etc. The limitation should be adjusted to the various lives and their activities, with which the law has to do. If law can protect life by fire-escapes, the necessity of stand-pipes, the abatement of the smoke nuisance, the ventilation of sewers, and the non-pollution of drinking water, certainly this more subtle and ever-present cause of degeneration and death, defective ventilation, even in its slighter degrees, should come under its fostering care.

I suggest that an effort be made to establish and maintain the equivalent of the following: For a living apartment, a minimum space of 1500 cubic feet per individual, and a minimum ventilation or change of air of 2000 cubic feet per hour per person. If this is not afforded in new houses, then transoms over outside doors and windows, preferably opening inward at the tops, should be required.[14]

A course for the study of ventilation should be made a prominent feature in all advanced schools and colleges, and the government should carry out the many investigations which will help to determine both the best means, and the proper and necessary limits of ventilation. This is one of the ways in which a national bureau or board of health, properly established and supported by our general government, could prove itself one of the most useful and worthy of all the different departments which are represented by secretaries in the President's Cabinet. Until such a national board is established, the government ought to found and liberally maintain a commission on ventilation of houses, public halls, schools, factories and mines. Properly conducted, such a commission could do incalculable good.

2. The table explaining the Angus Smith curve gives regular periods of time till the light goes out, and the extinguishment is divided into gradations from .1 per cent. carbonic acid up to 2 per cent. when the light goes out. It took .8 per cent. carbonic acid for the first quarter of extinguishment, .5 per cent. for the second, .4 for the third and .3 per cent. additional carbonic acid for the last quarter and total extinguishment.

3. Angus Smith: Air and Rain.

4. Dr. Angus Smith, in his "Air and Rain," in describing his sensations when confined in his experimental "lead chamber" containing 170 cubic feet, says of the chemical actions going on in the body: "They may take ten years to gather impetus to make their movements strong enough to produce sensations, and disease may be generated unknown to the individual, although it may kill him in the eleventh year, but if the chemical action began at first so violently as to produce decided sensations, he might be able to avoid it at once before it produced any abiding impression." After remaining in his chamber 100 minutes he found a reduction of oxygen to 20 per cent. and "the air had an unpleasant flavor or smell," and on entering it again after a minute he found "it extremely bad." He says "it took about four hours for the lungs to recover their tone."

7. Greswell: The Elimination of Tuberculosis Out in the Open. THE JOURNAL Feb. 3, 1900.

8. Parkes, in his Practical Hygiene, refers to the experience with horses in the French cavalry service and says that in ten years an annual loss of 190 per 1000 was reduced to 68 per 1000, by giving them more room in their stables, while in the English cavalry service, the change for the better by similar treatment was even more striking till the annual mortality was reduced to 20 per 1000.

Parkes, in his Practical Hygiene, notices the relation of increased mortality to density of population and adds that "its main concomitant condition is impurity of air from over-crowding,"—"especially among children whose delicate frames always give us the best test of the effect both of food and air."

10. Dr. de Chaumont's analysis, in Parkes' "Practical Hygiene," of the air in 11 barracks and hospitals showed an average excess of over 6 volumes carbonic acid per 10,000 and nearly twice that in the cells of four different prisons. Other and extreme analyses of air in rooms (in orphanage dormitories and detention places), with space per head all the way from 51 to 150 cubic feet, gave from 31 to even 72 volumes of carbonic acid to 10,000. The ratios were constantly greater, the more confined were the persons or animals.

11. Carmichael found in the Dublin House of Industry, crowded with children, that "the only causes for the excessive phthisis were the foul air and want of exercise."

12. In illustration, take notice of the dark lines on the plastered ceiling of a much used room. They are the interspaces between the laths where the dirty air has been sifted through.

13. That this education needed must be mainly directed to the ventilation of closed habitations is beyond any doubt: for Angus Smith's calculations, made in the cities of London, Manchester and Glasgow, showed so small a difference in the percentage of oxygen, as well as of carbonic acid, in the open places that we may conclude it is not so much the size of the city or the number of rooms in it, as it is the character of the rooms themselves. Parkes says "the colliers of Durham and Northumberland, where the mines are well ventilated, do not appear to suffer from an excess of lung disease, or to do so in a slight degreee." While as to "metal miners," he says that among them there comes to be, in advanced life, for males aged from 45 to 75, five times as many deaths from pulmonary disease "as for males exclusive of miners in Yorkshire." This latter evidence bears upon the quality of the dust in crowded places and rooms, which is organic to no small degree. Tichbone (Parkes' "Practical Hygiene") in a Dublin street, found it from 30 to 45 per cent. organic, and Chalvet, in a hospital ward in Paris, found the dust to be 36 to 46 per cent. organic matter. The sickening headache which some sensitive persons experience in, or after being in, a crowded theater, is probably wholly due to the rebreathing of excessive carbonic acid. "Crowd poison," as this air of crowded halls is sometimes called, undoubtedly contains much organic matter thrown off in the exhalations of the people there assembled. Even the moisture of these exhalations is not inconsiderable. Parkes averages an estimate of 211 cubic feet of air needed to maintain, in a state of vapor, the 25 to 48 ounces of water which a human being gives off in twenty-four hours' time, and he adds that when carbonic acid in the air has reached 7-10000 the smell of organic matter is generally perceptible, and it is "very strong" when 10-10000 is reached.

14. The variation of a proper law may be needed to suit the assembling of large bodies of people in halls, churches, etc., where occupancy is limited to a short time and a less space per capita seems to be allowable, or again where additional air is required, as in hospitals and certain work-rooms. But the building inspector, properly working with or under the Board of Health, should not only be possessed of a spirit of the law's righteousness, but should be a man of high intelligence and force.

DISCUSSION.

Dr. Phillips, of Washington, in the discussion, called attention to the experiments of Dr. B. W. Richardson[1], which served to confirm this contention for the life of the air. Richardson confined under glass, so they could be watched, four warm-blooded animals—a cat, dog, rabbit and pigeon, also two frogs—and gave them forty gallons of pure oxygen. He proved that the passing of the electric spark through the once used oxygen—which had killed or was killing the warm-blooded animals although only one-eighth of the oxygen had been consumed or was lost—restored the lost life or vivifying power. To quote Dr. Richardson:

> Oxygen, when breathed over and over again, although freed entirely from carbonic acid and other known products of respiration, loses its power of supporting life; the process of life ceasing not from the introduction of a poison, but as by a negation or a withdrawal of some principle extant in the primitive oxygen which is essential to life[2].

Whatever explanation we give for this, whether that there is a possible rearrangement of the molecules of oxygen due to respiration which makes it afterward unsuitable to respiration, or, as Dr. Phillips suggests, that our accepted molecular divisions of matter are possibly not ultimate, we are entitled, I think, to assume this experiment to be the strongest possible proof of the main argument of this paper, i. e., that the chief vitalizing principle of the atmosphere is annulled by deficient ventilation.

THE DIAGNOSIS OF APOPLEXY UNACCOMPANIED BY MOTOR PARALYSIS.*

WM. N. BULLARD, M.D.

BOSTON.

Apoplexy unaccompanied by motor symptoms is often overlooked by the general practitioner, or its manifestations are not understood, while even the specialist is at times in doubt in the more obscure cases. It is not, however, a very rare occurrence, although in most of the general and special text-books but little space is given to it. It seems, therefore, worth while to draw attention to these cases and to point out the symptoms and the method of diagnosis. This may best be done by briefly reporting a few cases of apoplexy where the motor symptoms were either very slight or absent.

Case 1.—J. B., a man 67 years old, born in Ireland, now living in Boston, having previously been in good health, though somewhat worried, had on Aug. 13, 1889, a sudden attack in which he turned blue in the face and seemed as though he were about to suffocate. He was raised up in his bed and shortly recovered. There seems to have been no marked loss of consciousness. The next day there was no paralysis of the limbs, no pain, no headache, but since the attack he has partially lost the power of speech and his mind seems confused. He complains of sense of weight on his head and his head feels heavy. He was seen on August 19, six days after the attack, and has stayed in bed most of the time since the latter, but can and does get up at times. Physical examination showed no paralysis anywhere. His mind was somewhat confused and there was some loss of memory and aphasia.

In this case the attack was evident and there could be little room to doubt the diagnosis. It seems doubtful as to how much loss of consciousness existed during it. While in the larger proportion of these cases there is a marked loss of consciousness accompanying the initial attack, this does not seem to be a necessary accompaniment. Attacks may occur which are not specially recognized at the time either by the patient or his friends.

The next case is typical of the more severe, and in many cases the most easily recognized, form of this trouble.

Case 2.—G. L., a male, 30 years old, clerk, was seen

[2] See also "Composition of Expired Air and Its Effects on Animal Life": Smithsonian Contribution to Pathology, by Billings, Weir Mitchell and Bergey.

*Presented to the Section on Neurology and Medical Jurisprudence, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

April 30, 1891. He is said to have been in good health up to the date of the present trouble. He probably had a slight attack three years ago. Eighteen months ago, while at supper, he had, without known cause, a sudden attack supposed to have been a shock, which was not considered important at the time, and since then he has been in his present condition. No paralysis was detected at any time. He has, however, been entirely unable to work, although he has tried to do so.

Physical examination showed him somewhat childish and a little weak-minded, excessively suave and courteous, and laughing constantly without cause; also unable to fix his attention. There is marked indistinctness in the pronunciation of words, so that at times he can scarcely be understood. He understands many things said to him but not everything. In attempting to read aloud he reads rapidly, but uses chiefly imaginary or meaningless words with here and there one of the real words interspersed. He can write his own name but can not write other names. There is no paralysis except an old iridocycloplegia on the right side, which existed previous to this attack. He grasps fairly well and his gait is normal; his knee-jerks are exaggerated and there is slight ankle-clonus on the left. On May 4 he had another shock and fell downstairs and was found unconscious. Since then he has been excited, talked much, was much annoyed with his family, and had delusions, though no hallucinations were detected. There was no paralysis.

By June 4, his mental condition had not improved. He had marked dementia, hallucinations of hearing, had become violent, and was committed to an asylum, where he grew rapidly worse and after a few months died.

This patient undoubtedly had syphilis.

The great seriousness of the mental condition in spite of the absence of paralysis is characteristic of many of these cases. How far the symptoms were the direct result of the apoplexies and how far any of them may have been due to the direct action of syphilis on the brain, can not be definitely determined, but inasmuch as the symptoms came on or grew worse in direct connection with the attacks, we are justified in the belief that the apoplexies were the principal immediate cause. This is also deducible from the evidence of other cases.

CASE 3.—A single woman, 46 years old, a tailoress, a patient of Dr. Samuel Breck, had some cardiac trouble six years ago and at times since has been "nervous," but no signs of hysteria have been detected. On Aug. 6, 1891, she went to the country, in her ordinary health; on the 14th she had epistaxis and was a little feverish; on the 17th, hemoptysis. She was feeling poorly, but on the 20th decided to return to Boston. When she awoke, on the morning of this day, her friend noticed that her face looked pinched, and it seems to have been drawn slightly to the left. It was also noticed that she readily allowed objects to drop out of her hands. Her mind was disturbed, she was incoherent and, contrary to her habit, she talked very loud. She did not notice or perceive things. She asked for her umbrella when she was holding it in her left hand and on being told that she had it in her hand, held out her right hand, which was empty, and said that she did not have it. She returned on this day to Boston, however, and seems to have walked and to have used her hands during the journey.

Since her return her mind has been affected. She has been complaining of many things, contrary to her usual disposition, and she has become obstinate and refuses advice. She tries to go to work, for which she is wholly unfit, and is said to have thrown her money away in the street. When seen on August 30 she had become violent and had to be restrained by force, and on this day refused food.

She is now excited, incoherent, mind much affected and weakened, but there is no paralysis anywhere. There is a diastolic souffle over the aorta and a presystolic one at the apex, with considerable cardiac enlargement, principally on the left.

This is probably a case of cerebral embolism. It illustrates well, however, the conditions often seen. The amount of paralysis which existed in the beginning was so slight, if any existed, as is probable, as to be neglected, and when later I saw the patient, it had wholly disappeared. The mental condition was at that time, and really throughout the whole affection, the prominent feature. There was no aphasia.

These cases differ pathologically from cases of ordinary apoplexy with motor symptoms, probably only in the seat of the lesion. Clinically we find usually a marked degree of mental involvement, on the whole more pronounced than in the cases with motor symptoms.

The diagnosis, while evident enough if the initial attack is seen or carefully reported, is often difficult when the patient is seen later. The mental weakness, the dementia and the loss of memory prevent the acquirement of an accurate history. The presence of partial aphasia might suggest a condition of this character, but does not necessarily prove it.

Apoplectic attacks may be, moreover, primary as regards lesions of the brain tissues, or secondary to them. In the first place, the cerebral symptoms are to be regarded as the direct result of the injury to the brain produced by the hemorrhage, thrombosis or embolism. In the second place, the cerebral symptoms may be due to the primary disease, such as paralytic dementia or tumor of the brain, and it may be very difficult or impossible to determine which are due to the primary disease and which, if any, to the secondary hemorrhage. In all cases whatsoever, of apoplexy or apoplectic stroke, it is important in the first place to determine whether it is due to disease of the intracranial blood-vessels from causes lying in themselves or outside of the cranium, or whether it is dependent on affections of the brain tissues. Sometimes both causes may act together.

The differential diagnosis of cerebral apoplexies without motor symptoms is usually easy when a proper history can be obtained. The most important evidence is the sudden onset of the symptoms. If motor symptoms, even though very slight, have been present, this favors the diagnosis. Where we see a patient some time after the appearance of the mental affection and where no history can be obtained, the diagnosis depends: 1, on the character of the mental impairment; 2, on the absence of symptoms pointing to paralytic dementia or to intracranial tumor.

In the cases of primary apoplexy—primary as regards previous affection of the brain tisues—which have come under my observation, the mental condition has been chiefly one of dementia more or less marked, with or without partial aphasia. Excited conditions have existed temporarily and hallucinations and delusions are not uncommon, but the dementia has been on the whole the more prominent condition. In mild cases this may be slight and the differential diagnosis between these and senile dementia can not always be made, if the history fails.

The second element in the differential diagnosis of the results of "primary" apoplexy from paralytic dementia or other cerebral affections is the presence or absence of the symptoms characteristic of these affections but not usual in the simple apoplexies. The condition of the pupils, the tremor, or the peculiar mental condition common in paralytic dementia, the severe headaches, the optic neuritis or optic atrophy of brain tumors, together with other symptoms common to these affections considered either separately or as a symptom-complex, will enable one to determine the pathologic condition.

89 Marlborough Street.

THE PLAGUE IN SAN FRANCISCO.

DOUGLASS W. MONTGOMERY, M.D.
SAN FRANCISCO, CAL.

The Journal has asked for the facts about the plague in San Francisco. The following are the cases, with their bacteriologic examinations, and experiments on animals as given by Dr. W. H. Kellogg, city bacteriologist, and Dr. J. J. Kinyoun, U. S. quarantine officer. I can endorse these tests and examinations, as I have taken a steady interest in them, and was deputed to follow them. Furthermore, the character of the men making these tests is above suspicion, and the scientific examinations made may be taken as correct, no matter what the conclusions drawn from them should be. They are here set before their proper jury, the medical profession.

The following reports of cases are made up from notes furnished me by Drs. J. J. Kinyoun and W. H. Kellogg: (Case 1 was reported in full in The Journal for May 19, p. 1236, and a full report of the result of the animal experimentation was also given.)

Case 2.—Chu Gam, aged 22, died March 15 at 723 Sacramento street. No clinical history was obtainable. The friends of the deceased gave conflicting stories as to his illness, some claiming that he had been sick over two months. When the body was first seen the face was enormously swollen and edematous; the skin of the whole body greenish black, and large blebs were present on the dependent portions of the body. The body had the appearance of having been dead a week. On section there was found a very little enlargement of the lymphatic glands. The lungs were dark and congested, but showed no evidences of pneumonia. The heart was very soft, with thin walls; there were no valvular lesions. There was considerable turbid fluid in the pericardium, in the pleura and in the peritoneal cavities. The spleen was enlarged, dark and friable, and the intestines showed evidences of inflammation. Microscopical examination of the blood and spleen demonstrated putrefactive organisms in large numbers and a few bacilli which had the appearance of the bacillus of plague. Attempts made to isolate this organism from the rest were successful. Cultures so isolated were sent to Dr. Kinyoun with the request that he inoculate an animal from these. Dr. W. H. Kellogg was informed that the animal died within 36 hours. of what appeared to be acute toxemia, and on examination very few organisms were found in the tissues except those at the point of inoculation. These gave a typical picture of plague.

Case 3.—Ng Ach Ging, aged 35, died March 17, at 905 Dupont street. No accurate clinical history was obtainable. The man was found dead, and immediately thereafter was turned over to the undertaker for burial. At the autopsy, performed forty-eight hours after death, the body was fairly well-nourished, but considerably discolored. On section, the glands were found not to be enlarged. The peritoneum contained about three pints of bloody fluid. The intestines were reddened, and the blood-vessels of the mesentery engorged. The spleen was slightly enlarged, dark in color and friable. The liver was slightly enlarged and congested. One of the most remarkable features was the complete transposition of the viscera. The spleen occupied the right side, the liver the left, the cecum being in the left iliac fossa. The lungs were edematous and hypostatically congested. The pericardium contained about two ounces of flocculent serum. There was also a considerable quantity of bloody serum in each pleura. The heart cavity contained several clots. Specimens were taken from the spleen and heart's blood for microscopical examination, which showed quite a number of putrefactive organisms present, and in addition thereto a short thick bacillus with rounded ends, which had the appearance of the bacillus of bubonic plague. It was readily decolorized by Gram's method. Animal inoculations were made from this material, which killed a guinea-pig within thirty hours and a white rat in five days. Drs. Kellogg, Kinyoun and Ryfkogel were present at the autopsy.

Case 4.—Lee Sun Kong, aged 47, died March 18, at Oneida place. When seen, forty-eight hours after death, the face was swollen and edematous. The skin of the whole body and part of the face and neck was greenish black. There was but little enlargement of the lymphatic glands. The lungs were dark and congested, but there were no evidences of pneumonia. The heart was soft and flabby, the walls of the ventricles thin, but there were no valvular lesions present. There was an inflammation of the peritoneum, the cavity of which contained one or two pints of turbid bloody fluid. The spleen was enlarged and very dark and soft. Microscopic examination of the blood and spleen demonstrated myriads of putrefactive organisms, and also a short thick bacillus with rounded ends, corresponding morphologically and in staining reaction to that of the bacillus of plague, and also corresponding in every respect to the organism found in the previous cases. This organism was not isolated in pure culture.

Case 5.—Law An, male, aged 38, a resident of California for thirty years, died April 24, in St. Louis alley, off Jackson street. This man had a large bubo in the left femoral region. Incision disclosed considerable bloody fluid and hemorrhages in surrounding tissues. Coverslip preparations showed among other organisms the bacillus of plague. Two guinea-pigs were inoculated, with the result that one died in fifty-eight and the other in sixty-one hours. Both these animals showed typical lesions of the plague, and the bacillus was found in large numbers in the spleen and heart's blood.

Case 6.—Lim Fa Muey, female, aged 16, died at Clay Street, May 11, seventeen days after the fifth case. She had a large bubo on the right side, in the femoral region, over which a sticky black plaster had been applied by a Chinese physician. The glands were as large as walnuts, dark, and the interior soft and mushy. Smears showed the specific bacillus, and its identity was confirmed by inoculation experiments on animals by Dr. Kellogg. Dr. J. J. Kinyoun also made inoculation experiments and got positive results.

Case 7.—Chu Sam, merchant, fifteen years in California, died May 11, at 717 Jackson street, aged 38. Dr. Kellogg saw this case on the day of death, with Dr. Wilson, at which time there was nothing visible to account for death, and the only suspicious thing about it was the heat of the body, which was quite noticeable, although twelve hours had elapsed since death. There was some distension of the abdomen with gas. There was a slight enlargement of the lymphatic glands in the femoral region, more marked on the left side, and these Dr. Kellogg removed for examination; but their appearance was so innocent that he set them aside and did not inoculate with them until forty-eight hours after removal.

The next day we went down to perform an autopsy and found the body in such a state of decomposition that we could not have recognized it as the same one we saw eighteen hours before, had it not been for a secret mark which we used to prevent substitution of bodies. The face was puffed up and edematous, the abdomen almost ready to burst with contained gases, and the skin discolored all over. The heart was very flabby, walls thin, and ventricles distended with gas; the lungs were normal, and the peritoneum was slightly inflamed. There was some fluid in both pericardial and peritoneal cavities. The speen was much enlarged, being six inches long, four inches wide and two thick. Color, a dark greenish slate with reddish patches. Smear preparations from the blood and spleen showed many organisms, but nothing resembling the bacillus of plague. Animals inoculated from the spleen died of toxemia, but no pest organisms could be demonstrated in them. The lymphatic glands, removed the day before autopsy, were slightly enlarged and showed slight hemorrhages into the gland substance; but they were firm and otherwise normal. A smear preparation showed a few organisms resembling the bacillus of plague, as seen in cultures. A guinea-pig which was inoculated with an emulsion of the glanduar substance died on the sixth day, with most typical lesions of plague. The spleen was at least ten times its normal size, covered with yellowish spots which, when examined, showed the presence of the plague bacillus in enormous numbers and in pure culture. The whole of the abdominal wall was edematous and there was an extensive coagulation-necrosis about the site of isolation. The organism was isolated from the spleen in a pure culture. The appearance of the body and also the pericardial lesions and general condition of the viscera were in every way identical with Cases 2, 3, and 4, already reported, in which difficulty was encountered in isolating the organism. It is believed, in view of the fact of this case, that if the glands had been taken from Cases 2, 3, and 4 as soon after death as in this case, and animal inoculations made from them, the same results would have been obtained. In this case, before the results of animal inoculation were known, the obscurity of the lesions seemed to be more in keeping with beri-beri than with bubonic plague.

Case 8.—On May 15 Dr. J. J. Kinyoun was informed by the assistant city physician, Dr. F. P. Wilson, that he had been notified of the death of a Chinese girl, which had occurred at the Pacific Hospital on the previous evening. The history obtained from the attending physician was that the girl, Chin Moon, was 16 years of age, a servant in a respectable Chinese family, at 730½ Commercial street, and had been ill for about five days. The girl was seen about three days before she died, and the symptoms then presented were headache, high fever, nausea, and pain in the right iliac region. The attending physician made a diagnosis of typhoid fever, and, observing the case to be very critical, had her sent to the Pacific Hospital; she was then in a moribund condition, and died on the following day. The attending physician at the hospital also made a diagnosis of typhoid fever and stated to me over the telephone that probably here was appendicitis. Dr. Kinyoun was invited to be present and assisted Drs. Kellogg and Wilson in making the post-mortem examination. An inspection of the body showed it to be well-nourished, and presenting no evidence of long illness. In the right femoral region there was rather an obscure swelling, which on palpation revealed a considerable mass of glands about the size of a walnut. Dr. Kellogg made an incision through the tissues down to this mass and demonstrated the correctness of the diagnosis. The swelling was a mass of enlarged glands. The tissues surrounding this mass of glands were edematous, containing a quantity of bloody serum. The mass of glands was dark, and hemorrhagic on section, and it was soft and necrosed in the center. Immediately on its removal Dr. Kellogg cut the mass in two, which on examination revealed the same organisms as had been previously observed in the glandular tissues of previous cases.

On the morning of May 14 Dr. Kellogg inoculated two guinea-pigs, weighing about 500 grams each, with an emulsion made from this glandular tissue. Death occurred in these pigs in sixty hours. Examination of guinea-pig No. 1 showed edema covering the whole of the abdominal wall. The peritoneal cavity contained a large quantity of bloody serum. The spleen was enormously enlarged, dark in color, and friable. Yellowish spots were observed on its free surface. The liver was enlarged and darkened, and the intestines were darkened and congested. The mesentery contained a considerable number of small hemorrhages in and about the mesenteric glands. The pleural cavity and the pericardium contained a considerable quantity of bloody serum. Coverslip preparations made from the point of inoculation, from the spleen, from the liver and from the heart's blood, showed an enormous number of short bacilli, having rounded ends, taking a typical bipolar stain. Cultivations were made from the several organs. In guinea-pig No. 2 the appearances were identical, with the exception that the spleen did not contain yellowish spots, as previously described in the case of guinea-pig No. 1. Coverslip preparations made directly from a portion of the mass of glands removed from the Chinese girl showed enormous numbers of a short bacillus with rounded ends, taking the characteristic stain. Cultivations were also made from this piece of gland, with the result that after thirty-six hours numerous colonies were observed on the surface of the agar and blood-serum. The cultures made from the several organs of the two guinea-pigs showed after thirty hours numerous small colonies on the surface of the blood-serum and agar tubes. These colonies were transparent, and when viewed under a low power were seen to be very slightly granular, and had a slightly irregular contour. Coverslip preparations made from these colonies gave identically the same picture as observed in the original preparations from the gland. The organism was non-motile. These pure cultures killed the animals injected with them, within sixty hours, and the post-mortem appearances were identical in every respect with those observed in the animals inoculated with a portion of the gland. Dr. Kinyoun, who was present at the post-mortem examination of this Chinese girl, took tissues directly from the body, and made independent examinations clear through and the above description is an amalgamation of the notes made both by Dr. Kellogg and Dr. Kinyoun.

Case 9.—Herr Woon Jock, aged 53, male, laborer, married, ten years in California, had recently arrived from Stockton. He died May 14, at 740 Pacific street. Examination showed a bubo on the left side in the femoral region. The skin over the swelling was slightly discolored. The gland was dark and mottled on section, contained considerable serum, and the glandular tissue was soft and mushy. The smear preparation showed great numbers of the bacillus of plague, the identity of which was confirmed by animal inoculations.

Case 10.—Dang Hong, aged 40, male, laborer, a resident of California for the last sixteen years, died May 29, at 706 Pacific street. There was a large fluctuating swelling under the left side of the jaw, and a slight enlargement of the glands in the femoral region. Dr. Kellogg cut down on the glands on the left side and found them necrosed, and some thick pus present. A smear preparation showed the plague bacillus in the glandular tissue from both sources. The next day at 11 a. m. an autopsy was performed, at which were present Drs. Shrady, Montgomery, Kinyoun, Wilson, Morrissey, Cable and Kellogg. The lungs were normal, the heart muscle pale and flabby. About six ounces of bloody serum was found in the pericardial sac. The pleuræ contained about a pint each of the same fluid, and the peritoneal cavity three or four pints of bloody-serum. There were no lesions of Peyer's patches, but congestion of the peritoneal coat of the small intestine in spots. The great omentum showed intense congestion; the spleen was perceptibly enlarged and its substance a reddish brown color; and the mesenteric glands were enlarged. Animals were inoculated with the emulsions made from lymphatic glands, by Dr. Kinyoun and Dr. Kellogg, independently, and all died with typical plague infection.

Case 11.—Chen Kuey Kim, cigarmaker, single, aged 49, died June 2, at 10 a.m., at 817½ Clay street, between Dupont and Stockton streets. He had lived twenty-five years in California. An unreliable history of nineteen months' illness, with cough, was obtained from the undertaker and the Six Companies' physician. It was also stated that he had been sick for four or five days before death. The body was that of a large, well-built and well-nourished man. There was an incision in the left groin and on the right side of the neck from which the lymphatic gland had been removed. The integument was beginning to turn dark all over the body, but was more marked on the face and neck. The median incision passed through about an inch of fat. The lungs were dark and congested, but otherwise normal. The pericardium contained about 60 c.c. of bloody serum. The heart was a trifle flabby, but showed no valvular lesions; peritoneum dry; spleen enlarged and showing petechial hemorrhages beneath the capsule. A cross-section showed numerous yellow dots all through its substance, which was soft and friable. The mesenteric glands were enlarged and showed evidence of inflammation. Kidneys normal. By enlarging the incision found in the left groin a lymphatic gland about the size of a hazel nut was found, which as necrosed. Microscopical examination of this gland and of the heart's blood and spleen showed the presence in enormous numbers of the plague bacillus.

The autopsy on this case was performed by Dr. Donnelly, assistant bacteriologist, and was witnessed by Drs. F. P. Wilson, assistant city physician, Dr. Henderson, member of the State Board, and Dr. Kellogg. Drs. Henderson and Wilson accompanied Dr. Kellogg to the laboratory, where they were joined by Drs. Kinyoun and Baum, and where the preliminary examination of the blood, spleen and lymphatic glands was made and witnessed by the above named gentlemen. A coverslip preparation of the blood stained with thionin showed a marked leucocytosis and the presence of large numbers of the bacillus pestis, which were short rods with rounded ends, bipolar staining and frequently occurring in pairs. The Gram method of staining was also tried and they were found to decolorize perfectly. The spleen and lymphatic glands were simply crowded with large masses of the same bacilli, which was enough in itself to establish the diagnosis. To make assurance doubly sure, a guinea-pig was inoculated with an emulsion made from a piece of the spleen, with the result that it promptly died on the sixth day with the most typical and positive appearance of plague. The organism was recovered from the organs of the guinea-pig in pure culture and has been fully identified. Another pig was inoculated with this culture with the same result. Dr. Henderson, of the State Board of Health, witnessed preliminary examination of this case and took away with him slides which were made and sealed in his presence.

Case 12.—Jay Man Tong, male, aged 60, merchant, residing at 759 Clay street, a high official in the Six Companies. According to a certificate signed by white physicians employed by the Chinese, he had been sick for a year, and had died June 9, at 3 a. m. of angina pectoris; was said by his friends to have suffered from pain in the chest and cough for a year previously, and that his death was sudden.

Autopsy was performed June 9, at 1 p. m. The man was five feet ten inches in height, and weighed about 175 pounds. Body was well-nourished. Impaired tricuspid valve. Blood, in heart cavities, fluid. Two or three ounces of clear serum in the pericardium. Lungs normal. Some bloody fluid in the peritoneal cavity. Intestines were dark—distended with gas—and showed evidences of intense inflammation. Injection of vessels of mesocolon. Appendix normal. Spleen slightly enlarged.

Dr. J. J. Kinyoun reported on the animal experiments in the case of Jay Man Tong as follows:

June 10, 1900.—Guinea-pig 1, inoculated with emulsion of mesenteric glands stated by Dr. Kellogg to have been taken from the body of the Chinese, Jay Man Tong, who died the day before. Guinea-pig dead in 46 hours. Autopsy showed considerable edema at the point of inoculation, a slight enlargement and marked congestion of the inguinal glands, particularly on the right side. The spleen was not enlarged. The lungs were in a state of commencing pneumonia. The peritoneum was dry.

Coverslip preparations made from the point of inoculation, the spleen, heart's blood and lungs showed a large number of bacilli, short and thick, having rounded ends, with a tendency to bipolar staining. Cultures made from the spleen and heart's blood. After about sixty hours, the several cultures were examined and found to contain a mixture of several organisms, many of which were the same morphologically as those found in the tissues of the animal. It became necessary to again make secondary cultures to isolate the several species.

June 11.—White rat, half grown, was inoculated with emulsion of the gland from Chinese dead June 10. Rat died after eighty-four hours.

Autopsy showed marked edema, and extensive suppurative necrosis of the abdominal wall, at the point of inoculation, some peritoneal effusion, spleen enlarged and dark in color. The kidneys were the seat of small abscesses. Coverslip preparations made from the point of inoculation, spleen, kidneys and heart's blood, showed enormous numbers of a short thick bacillus having rounded ends, bipolar staining, which were decolorized by Gram's method. Cultures made from the heart's blood, spleen and kidneys were examined after forty-eight hours, when large numbers of colonies of several varieties of bacteria were found. The colonies were so numerous and overgrown that it was impossible to isolate them, so secondary cultivations were necessary.

After several days colonies were isolated which corresponded in every way with those of the plague bacillus. June 24, 1 a. m., a half-grown white rat was inoculated with this culture. Animal dead June 27, 80 hours. Autopsy made June 28 in the presence of Drs. Ryfkogel and Fagan. There was a considerable area of suppurative necrosis at the point of inoculation, and an extensive edema covering the whole abdominal wall. The intestines were dry; spleen enlarged, dark in color and friable. Coverslip preparations made from the spleen, point of inoculation and the heart's blood, showed a short, thick bacillus, having rounded ends, which took a characteristic bipolar stain with thionin. It was decolorized by Gram's method.

Cultivations were made from the spleen and heart's blood and showed at the end of forty-eight hours characteristic colonies of the plague bacillus.

Besides the above cases, there were a number where the indications pointed strongly to the plague, but where either from advanced decomposition or superinfection, the plague bacillus could not be isolated.

The only bacteria which, in their size, shape and coloring peculiarities, might be mistaken for those found in the above cases, are those of hog cholera and those of septicemia of rabbits. Neither the hog-cholera nor the rabbit-septicemia bacilli, however, would be pathogenic for rats; they are therefore excluded as sources of error. The points of resemblance are very few, but Dr. Ryfkogel, to settle the question, inoculated a pigeon with plague bacilli from those cases, with no result. If they had been chicken-cholera or rabbit-septicemia bacilli, they would have killed the pigeon. The plague bacillus is innocuous to pigeons.

On the other hand, every fact speaks for a diagnosis of plague, and nothing valid has, up to the present, been brought against this view.

The following are the arguments against the existence of plague in Chinatown:

1. No two cases have been reported as occurring in the same house; 2. No diagnosis of plague had been made on a living patient; 3. The number of cases found has been too small for so virulent a disease as the plague, and the death-rate in Chinatown has not been notably increased.

In answer to the first objection, it must be remembered that the habitation of a given Chinaman in our Chinatown is a difficult matter to fix, especially at such a time as the present, when they are alert and suspicious. I believe it could only be accomplished by police registration similar to that practiced in European countries.

It is true that no diagnosis of plague has been made on a living patient, and I have it from a China woman, who is an educated physician, that no living patient having the plague will be found until the number of sick is so great that they can not be hidden. At one time lately the corps of white inspectors, all educated physicians, went over Chinatown three times in five days, from Monday till Friday inclusive, without finding any one sick. During three of these days, Monday, Tuesday and Wednesday, no deaths were reported in Chinatown; then immediately thereafter, two and three deaths a day were reported for several days. It is absurd to suppose that in a population of between twenty-five and thirty-five thousand, even when deaths were occurring, no one was sick.

In answer to the third argument against the plague being in Chinatown, it must be remembered that plague does not enter a community rapidly, but slowly and insidiously, and it is not till many disease foci are established that the disease assumes the proportion of an epidemic. It is thought by some well-informed men that the plague strikes a community with the same rapid malignancy that it attacks an individual. This is not so. It advances slowly in a community, attacking house after house. The people living in an infected house fall ill of the disease, but not even all the people in such a habitation contract the plague, or at least not all at the same time. Doctors and inspectors, as is well known, for instance in Bombay, visit such houses with impunity, but do not linger in them.

The outlook for the future is not bright. The plague has a tendency to subside during the summer, but probably it will appear with increased violence next winter. The board of health has done and is doing all the sanitation possible with the meager funds at its disposal, and there is some agitation on foot to put Chinatown in a thoroughly sanitary condition. The heart of the people is, however, not in the work, and they refuse to believe the plague is present. The daily press keeps up a steady abuse of the board of health, and of Dr. Kinyoun, on one hand, and urges several fantastic, impracticable schemes for cleaning Chinatown, on the other. Glimmerings of the truth, however, occasionally filter through. They protest too much that the plague is not present, and on June 29 last, one of the bitterest enemies of the board of health, the *San Francisco Chronicle*, in an editorial, even spoke of Chinatown as "the infected property." Infected with what?

It is a wise custom of the medical profession not to answer abuse appearing in the daily press by return abuse, and the board of health, Dr. Kinyoun and Dr. W. H. Kellogg have acted up to the best traditions of the profession in this respect. They have done and are doing their work well, without paying any attention to the papers.

SPECIAL ARTICLE.

RELATION OF PHARMACY TO THE MEDICAL PROFESSION.*

VIII.

ELIXIRS.

In the administration of liquid medicines, eligibility of the preparation is of importance scarcely secondary to that of therapeutic efficacy. With the advent of the elixirs, the former impalatable mixtures and decoctions were made not only more palatable but often even inviting to the other physical senses—odor and color. For about twenty years—1870-1890—the elixirs enjoyed great medical favor, they with the fluid extracts being the chief product of nearly a score of manufacturing pharmacists of national reputation. But like many other good things, the "elixir idea" became a craze; everything desired was presented in this form until drugs of the most repugnant taste, as well as agents of the most incompatible character, were associated in the form of elixirs. As the preference for the elixir rested primarily upon its name, suggestive of something sweet and agreeable, there was much rivalry engendered through the desire to present the most elegant and palatable preparations, with the result of sacrificing therapeutic quality and strength for elegance and taste.

---

* The first of this series of articles appeared in The Journal of April 21.

THE DECADENCE OF ELIXIRS.

As a consequence the elixirs fell into disrepute and, with but few exceptions, are now comparatively seldom used. And yet the elixir is the best form of administration adapted to a great many medicinal agents and their combinations, if proper care and judgment be exercised in their selection. To produce an agreeably flavored saccharine vehicle, containing sufficient alcohol to make it a good solvent, and to promote the prompt absorption or effect of the medicinal agent, and, when required, associated with adjuvants and correctives to mask the taste and to modify their effect, is to realize the ancient motto of Asclepiades: *Curare, cito, tuto et jucunde.*

The decadence of the elixirs was also greatly encompassed by the various solid forms of preparations, modifications of pills, such as tablets, which have for some time been the ruling fashion. The tablets have much less to commend them as a general form of medication than have the elixirs, but, unlike the elixirs, neither incompatibility nor insolubility needs to be taken into consideration in their preparation. In the elixirs the most apparent of such pharmaceutical objections were self-evident, but in the tablets "everything goes," and to this fact, more, perhaps, than any other, do the tablets owe their popularity.

CASCARA PREPARATIONS.

While there is no end of cathartics, and numberless combinations of these in pill, granule and tablet-form, there has always been a desire for a liquid laxative of pleasant taste, prompt but agreeable in effect. For children, women and persons of sedentary habits generally, such a preparation seems almost a necessity. Until the introduction of cascara sagrada some twenty-five years ago, this want was filled chiefly by senna and, on the Continent, by Rhamnus frangula, somewhat similar in its action to cascara sagrada (Rhamnus purshiana). The value of senna, aside from its immensely popular domestic use, is attested to by the medical favor even such proprietary medicines as Syrup of Figs have enjoyed. As has already been pointed out, that largely used domestic medicine "Castoria" is substantially a syrup of senna. The official syrup of senna will be found a superior preparation, provided it is made strictly according to the process of the Pharmacopeia. With reference to the cascara preparations, there are several things to be taken into consideration in determining the activity of its various preparations and their indications. No experienced physician will prescribe such gentle laxatives as senna or cascara sagrada when a strong cathartic or purgative is indicated, and yet fault is often found with cascara preparations because they do not act in those cases in which a saline purgative, or castor-oil, should have been administered. The very mild action of cascara is what makes it valuable in habitual constipation, its administration gradually restoring the intestinal movement to its normal condition and it should therefore not be administered when irritants, such as aloes, colocynth, podophyllum and other resins, are indicated. Owing to the great demand for cascara sagrada, to its being indigeenous to only a limited area on the Pacific slope, and to the fact that the bark should be collected under certain conditions, an active reliable bark is not always obtainable in the drug market, and an inferior, sometimes worthless, specimen of the drug is used for its preparations. To disguise its extremely bitter taste, various drugs have been used, chiefly licorice, and also aromatics and correctives. More recently the so-called tasteless preparations of cascara have been introduced. These are made by combining magnesia with the drug, which modifies the bitter taste, and, it is said, also its cathartic action. The first of these preparations was the "Cascara Cordial," whose formula was published whn introduced by the manufacturers. It contained berberis aquifolium with licorice and aromatics. Other similar preparations are: "Arolax," "Elixir Purgans," "Elixir Purgative," "Kasagra" and many different brands of "Cascara Aromatic" of which the "Extractum Rhamni Purshianæ Fluidum" of the National Formulary is the type. This is the fluid extract of cascara deprived of bitterness, containing some licorice and flavored with compound spirit of orange.

The following elixirs are also given:

Elixir Rhamni Purshianæ, N. F.

℞.	Fl. ext, rhamni pursh	ʒ6¼	25
	Elixir taraxaci comp	ʒ18¾	75
M.			

Elixir Rhamni Purshianæ Compositum, N. F.

℞.	Fl. ext. rhamni pursh	ʒ3⅛	12	5
	Fl. ext juglandis	ʒ1⅝	6	5
	Syrupi senna	ʒ6¼	25	
	Elixir taraxaci comp	ʒxxv	100	
M.				

The dose of either of these is one to two teaspoonfuls.

VIRBURNUM COMPOUNDS.

There are many preparations of virburnum of similar composition. While Virburnum prunifolium or "black haw" was not introduced into general practice until about twenty-five years ago, the Virburnum opulus or "cramp bark" had long been used as a uterine tonic and sedative, especially by physicians in the Central States. Associated with these were the "false" and the "true unicorn root," Aletris farinosa and Helonias dioica; "life root," Senecio aureus; "Wildgam," Dioscorea illosa; "skullcap," Scutellaria lateriflora; "skunk-cabbage," Symplocarpus fœtidus, "blue cohosh," Caulophyllum thalictroides, "squaw vine," Metchellarepens; Hydrastis Canadensis and similar indigenous drugs.

Formulas for various decoctions, tinctures, extracts and syrups of these drugs have appeared in the American Dispensatory and have been largely employed by the so-called eclectic physicians. Many similar preparations are offered at the present time under more or less descriptive or therapeutically suggestive names.

Among these may be mentioned: "Aletris Cordial," "Helonias Cordial," "Dioviburnia," "Utero-tonic," "Eumetria," "Liquor Uterans" and "Hayden's Virburnum Compound." The latter, prepared after the formula of Dr. Hayden, is the most popular of all these preparations. The famous "Lydia Pinkham's Vegetable Compound" is of somewhat similar composition. As will be seen, this group represents only the more simple of galencial preparations, or mixtures, and does not require any special skill in manufacture. The drugs are easily obtained from which the preparations are made by extraction with suitable mentsrua, as in the following from the National Formulary:

Tinctura Viburni Opuli Composita.

℞.	Virburnum opulus		
	Dioscorea, āā	ʒviiiss	35
	Scutellaria	ʒiiss	10
	Cloves	ʒxiiss	50
	Cinnamon		
	Glycerin, āā	ʒxviss	65
	Alcohol	℥xxiv	750
	Aquæ, q. s. ad	℥xxxii	1000
M.			

Or a prescription may be formulated:

℞.	Fl. ext. viburni opuli	m.160	10
	Fl. ext. dioscoreæ		
	Fl. ext. scutellaria, āā	m.80	5
	Tinct. cinnamomi		
	Tinct. caryophylli, āā	ʒ6¼	25
	Glycerini	ʒ2½	10
	Elixir adjuvantis	ʒ30	120
M.	Sig. c. p., t. i. d.		

Somewhat similar is the well-known preparation "Celerina," the "nerve tonic and stimulant," said to contain in each fluidram 5 grains each, coca, kola, virburnum and celery.

The National Formulary has the following:

Elixir Apii Graveolentis Compositum.—(Compound Elixir of Celery.)

℞.	Fl. ext. apii sem.		
	Fl. ext. viburni prunifol.		
	Fl. ext. erythroxylon		
	Fl. ext. sterculide, āā	ʒiss	6
	Elixir aromatici, q. s.	ʒxxv	100

In order to prevent confusing the botanic name "Apium" with "Opium," the full name of the celery plant, Apium graveolens, has been selected for the title of this preparation.

"MERELY MIXTURES."

While these preparations are largely prescribed and no doubt useful, the various drugs from which they are prepared have nearly related virtues, and the different combinations, it would appear, could be formulated as wanted, with better advantage to the physician, patient and pharmacist. The fluid extracts and tinctures of these drugs, prepared from the best quality of drugs, are easily procurable by any pharmacist, and so the preparation becomes excedingly simple. This group may easily be regarded as the class of preparations which have no *raison d'etre*, as pointed out in the last article of this series by a well-known manufacturer. They are "merely mixtures," requiring no skill in their preparation. They present no originality in combination, but when a new brand appears under a fancy name it adds to the trials of the physicians, who have, to stand in the breach and have their time and patience frittered away by the advance agents, as shown by Dr. Witherspoon in his Oration on Medicine at the last meeting of the AMERICAN MEDICAL ASSOCIATION. These unnecessarily load up the pharmacist's shelves and become a burden to him. The prices at which they sell are usually out of proportion to the absolute cost. The pharmacist is required to purchase full original bottles of each of a score or more of these different named preparations in order to dispense a small quantity occasionally, the remainder being left on his hands, until they deteriorate. He naturally complains because he is required to keep on hand so many of these similar preparations, which he could mix for the physician. He also objects because, as a rule, these preparations are introduced by those who have no interest in either pharmacy or medicine.

This class of preparations have nothing to commend them to medical men and soon degenerate into popular medicines through their suggestive titles and the many often imaginary ills they are recommended to cure.

Therapeutics

Dionin.

Smithwick has used dionin as a cough remedy in 30 cases, of which he has records: 12 of chronic bronchitis, 7 of phthisis, 3 of whooping-cough, and 8 from various other causes. Sixteen were apparently cured, 9 benefited, and only 5 not benefited. He has never noticed any unpleasant effects, in which it has a decided advantage over morphin and can be safely adapted for children where morphin should not be used. He has never noticed any tendency to habit in its use even when it is prolonged. As an analgesic it is inferior to morphin.—*Merck's Archives*, June.

Aqueous Extract of the Suprarenal Gland.

In *Merck's Archives* for June the physiologic action of suprarenal gland extract is first briefly stated by Somers, who claims that the non-toxicity of the drug renders it especially applicable for inflammations of the mucous surfaces. In no case has he observed idiosyncrasies toward the drug, and besides being harmless itself, it to a marked extent prevents the toxic effects of cocain. The solutions are non-irritating and have no deleterious after-effects. Its action being local, there is no danger of contracting a useless habit. The great difficulty has been in obtaining a stable solution that will retain its power and yet remain sterile. Putrefaction, however, does not destroy its special qualities, even after an extreme degree of decomposition. Glycerin in from 10 to 25 per cent. will prevent putrefaction for several days, and in the following formula of Ingals it will remain undecomposed from three to five weeks:

℞.	Adrenal	gr. xv
	Boric acid	gr. iv
	Cinnamon water	ʒi
	Camphor water (hot)	ʒii
	Boiling water, q. s. ad	℥ss

M. Macerate four hours; filter.

This is useful in mild congestions, but can not be depended on to control hemorrhage or subdue active inflammation. Alcohol, in proportion of 1 minim to a dram in the aqueous solution, will preserve it for three days. Salicylate of soda, 1 grain to a dram, will enable it to keep from four to six weeks, and carbolic acid in the same proportion will preserve it several months and not impair its qualities. The following formula as a local application in hay-fever is often productive of marvelous results and does not lose its physiologic activity for several months:

℞.	Adrenal	gr. xx
	Phenic acid	gr. ii
	Eucaine B	gr. v
	Distilled water	ʒii

M. Macerate ten minutes; filter.

Used alternately with orthoform it will prove of value in hay-fever and painful congestion of eroded mmbranes. The activity depends on the contractile power of the extract on the small arterioles and basement membrane, and it is more prominent where it can remain in contact with the tissue for several minutes. When used to prevent hemorrhage it should be applied to the parts, then cocain applied and the adrenal again applied. In operations where it has been used the results are in every way more satisfactory than when not employed, and it seems to enhance the anesthetic effect of cocain. Somers concludes that aqueous extract of suprarenal glands is the most powerful astringent and vasomotor constrictor that we possess. Its action is peripherally exerted directly on the vessel-walls and is limited only to parts with which the drug comes in contact. It is non-toxic, non-irritating, and does not cause habit or tolerance. It prevents the toxic effects of local anesthetics by retaining them in the tissues and preventing absorption, and while it readily decomposes, it does not lose by this its physiological activity. It first blanches and then contracts mucous tissues and will subdue active or passive inflammation. Its activity is not impaired by boiling, and it may be readily sterilized in this way, while carbolic acid will preserve the solutions indefinitely and not impair their value. It will prevent primary. and greatly lessen danger of secondary, hemorrhage. Its action is rapid, manifesting itself in twenty seconds, attaining its maximum in five minutes and lasting from one and one-half to twenty-four hours. It increases the tonicity of the parts, auguments the action of other drugs, especially cocain, and diminishes post-operative swelling. It markedly restricts exuberant granulation tissue wherever situated, and, finally, it diminishes scretion and aids in more rapid healing.

Treatment of Epididymitis.

That so large a majority of patients afflicted with epididymitis are compelled to remain on their feet has caused H. M. Christian, in the *Therapeutic Gazette*, March 15, 1900, to describe the treatment for this affection followed in the University and Polyclinic hospitals of Philadelphia. The testicle is first gently massaged with a small amount of 20 per cent. guaiacol ointment made up with lanolin. The same ointment is then spread on lint and applied over the affected testicle and the whole of the scrotum is wrapped in absorbent cotton. A snugly-fitting, laced suspensory bandage is then applied. This treatment is repeated every other day for about six days. By this time, inflammation has subsided, the testicle has lost its sensitiveness and an ointment made up as follows is substituted, the application being made in the same manner.

℞.	Ung. hydrarg. Ung. belladonnæ Ichthyol Lanolin, āā	℥ii

If the patient can be kept in bed two or three days and the affected parts *poulticed, or kept enveloped in moist heat*, frequently applied, and such hygienic medication administered as the case requires, before beginning the guaiacol treatment, a more speedy relief will follow. However, in the last few weeks he has treated sixty acute walking cases, and in all but six great relief from pain followed within twenty-four hours.

New Facts Regarding the Use of Croton

A. K. Bond, in the *Thera*
gives the results of recent
drug. It has been the custom

resort in extreme cases, and in nearly every instance the text-books state the dose as one drop. Nearly the same description is given in all text-books, namely, that it is a "violent drastic and hydragogue cathartic, which may excite an erythema, even when taken internally." For these reasons it has been shunned. The prejudice, he finds, is largely due to the dose employed. A drop of croton oil is in proportion to forty grains of calomel or one grain of opium. Confining himself to one-eighth, or one-sixth of a drop, a gentle purgative action is secured, without violent or even disagreeable results. As with many drugs, caution must be used to learn a person's tolerance of larger doses; and contraindications to its use are pronounced heart weakness or inflammation of the digestive tract.

He finds little to corroborate the idea that is extant regarding the uncertainty of croton oil, and all such uncertainty is within the power of the pharmacist or manufacturer to overcome. To avoid any such uncertainty of action, he supplies the drug personally, when required, from a vial of known strength. He has found the drug to act harshly when it followed ineffectual doses of other purgatives. The simplest method of administration is by bread pill made on the spot. In moderate doses, he finds that croton oil produces two or three small, usually dark, discharges, with very little, if any pain. He has never known hardened feces to follow its use, and thinks the drug must excite the outflow from the intestinal glands.

Pericarditis in Bright's Disease.

Bose *(Nouv. Montpellier Méd.)* concludes an article on pericarditis in Bright's disease with the following treatment:

For the heart complication, dry cups with repeated injections of ether, the latter remedy being sufficient to control the dyspnea.

For the underlying uremia, purgative enemata, wet cups over the kidneys and general blood-letting, followed by intravenous injection of saline solution.

Not too much is to be expected from the above regimen, because the double intoxication of uremia and the pneumococcus rendered all hope feeble.

To Relieve Neuralgia of Phthisical Patients.

Capitan prescribes the following ointment. A very small quantity is lightly applied and the part covered with some impermeable material and absorbent cotton. The application must be discontinued as soon as the skin becomes even slightly reddened:

℞.	Guaiacol	
	Methyl, salicylatis, āā	gr. lxxx
	Ext. belladonnæ	gr. iiiss
	Ext. opii	gr. iv
	Vaselin	
	Lanolin, āā	℥ss

In very acute cases menthol (15 grains), antipyrin (30 to 45 grains), or potassium bromid (80 grains) may be added.—*Gaillard's Med. Jour.*

Treatment of Mosquito Bites.

For the treatment of mosquito bites the application of aqua ammoniæ may counteract the infectious principle, but this is doubtful, for it does not penetrate the tissues, as did the insect's bill. At any rate it reduces the suffering if applied with a little rag and left *in situ* a few moments.

Menthol sometimes affords considerable relief, the crystalline, solid or camphoraceous substance being rubbed over the surface.

Neal highly recommends the following mixture for local applications:

℞.	Pulv. ipecacuanhæ	ʒss
	Spir. vini rectif.	
	Etheris, āā	℥ss

M.

Ottinger affirms that ammonia is of little benefit, and that the best results are obtained from the application of ichthyol. In numerous bites and stings of flies, gnats, bees, wasps, etc., he found that it quickly and surely caused the phenomena of inflammation—which he attributes to its vasoconstrictor action—to subside. It is best applied pure in a quite thick layer, though it may be used in the form of an ointment.

Morris also suggests painting the bites or stings with a saturated solution of either camphor or salol in ether; or a mixture of 30 grains each of salicylic and benzoic acids in 7 drams of collodion, may be tried. Brocq and Jacquet recommend the following as effective for the bites of fleas, mosquitoes, gnats, sand-flies, mites, etc.;

℞.	Camphorated oil of chamomile	parts 100
	Liq. styrax	parts 20
	Peppermint essence	parts 5

M. Apply.

When many bites have caused violent local tumefaction and congestion a cold lead-water poultice forms a very soothing application. Lemon juice is also useful.—*Monthly Cyclopædia of Practical Medicine.*

Digitalis in Pericarditis.

Baginsky, in his Berlin clinic, has found sixty cases of pericarditis in children, of which twenty-four were of rheumatic origin. Careful percussion is necessary to diagnose the condition. It is rare to see a case of polyarthritic rheumatism without involvement of the heart, and the lesions of the pericardium are proportionate to the number of recurrences. Salicylic acid he has found to fail in these cases, but he has obtained good results, notably in the relief of dyspnea and edema by administering digitalis and diuretin.—*Sem. Med.*

Nephrolithiasis.

Dr. Charles G. Cumston, of Boston, Mass., in the *International Med. Magazine,* says that in the attempt to dissolve renal concretions by alkalines he has frequently ordered the following combination, with apparently happy results:

℞.	Sodii phosphat.		
	Sodii bicarb., āā	45	
	Lithii carbonat	10	

M. D. in scatul. Sig. A dessertspoonful dissolved in a glass of water thrice daily.

Danforth speaks most highly of potassium citrate in the dose of two grams every three or four hours, and the writer has prescribed it with good results, as follows:

℞.	Potass citrat	1	
	Sodii bicarb		5
	Lithii carb., efferves		25

M. In chart. No. 1. D. tal. dos. No. xx. Sig. Take four or five powders daily in a glass of water.

When there is pyelitis the writer has given urotropin, dose 5 grams in water several times daily, on account of its real antiseptic properties in the genito-urinary tract, or the following formula:

℞.	Acidi benzoic.		
	Natrii salicylat., āā	3	
	Aquæ chloroformi	90	

M. D. Sig. To be taken in four doses during the day.

For severe hematuria we have employed ferripyrin in several cases, with a satisfactory outcome, combined as follows:

℞.	Ferripyrini	1	
	Tinct. gentian comp.	10	5
	Syr. cort. aurant	90	

M. D. Sig. Take a dessertspoonful every two hours.

Or:

℞.	Ferri albuminat		25
	Acidi tannici		05
	Sacchar. alb		5

M. In chart. No. 1. D. tal. dos. No. xv. Sig. Take three or four powders daily according to indications.

A cure at some mineral resort is really of some value, and at these places the advantages of producing oxidation of uric acid by baths, strict attention to diet and a well-directed exercise, tend to have an excellent action.—*The Med. Bull.*

Treatment of Prostatis.

Abeille, of Nantes, has been very successful with an original treatment of gonorrheal prostatitis which he describes as follows in the *Revue Clin. d'Aur. et de Gyn.* After securing anesthesia of the urethra with cocain, he introduces a Nélaton sound, No. 12, and connects it with a reservoir containing potassium permanganate at 1 per 4000 or 1 per 2000, according to the ability of the urethra to support it, at a temperature of 35 to 38 C. The liquid passes through the sound up to the sphincter and flows out between it and the walls of the canal. When the penile portion is thus well irrigated, the sound is inserted through the sphincters, without interrupting the flow of the liquid, and the bladder receives the same cleansing. If there is a strong desire to urinate, the urine can pass out through the sound. With this treatment Abeille has aborted many a case of prostatitis which would have suppurated if left to itself.—*Revue Internat. de Méd. et de Chir.*

Strychnin in Alcoholic Neuritis.

E. R. Houghton (*Med. Rec.*) cites the case of a young man suffering from alcoholic neuritis, for which he was treated ineffectually for over a month. Finally he was put on 1/10 gr. strychnin four times a day, and improvement began at once. Two weeks after this treatment was begun the patient was about on crutches, and in two weeks more was walking about. At the present time (two weeks later) he is entirely well.—*Merck's Archives.*

Apomorphin.

In the June number of *Merck's Archives*, Douglas states that apomorphin acts as a prompt and well-nigh infallible hypnotic, if given hypodermically in doses of 1/30 gr. In some patients, however, this is too large and produces nausea. The proper dose is one that should just fall short of this effect, and 1/30 gr. being about one-third of the ordinary dose, it is naturally safe. He has found that it becomes inert if given in a saturated solution of boric acid, of which fact he has not discovered any mention in the medical literature. There is no danger of producing habit, as an overdose at once causes emesis. The advantages it possesses besides safety and lack of habit production, are its promptness of action in producing sleep in less than half an hour, its almost absolute certainty of action, even in the wildest delirium, and the refreshing character of the sleep.

Treatment of Uremic Attacks.

Use hypodermoclysis, provided the symptoms are not pressing and there is no trouble with absorption because of edema; when the danger is pressing, or edema is present, even in a very slight degree, use intravenous injection. In a large proportion of cases the patient should be bled, particularly if nervous excitement or convulsions are present or threatened, because this will relieve cerebral congestion, and aid in the elimination of toxins and in the absorption of the fluid from the subcutaneous tissues; or if intravenous injections are used, it will make room, so to speak, for the artificial serum. I believe this is of importance, unless the circulation is evidently very feeble from profound debility and anemia. Again, it is of great importance to aid sweating by the use of the hot pack, using care that heat stroke is not produced; but this again should not be used unless the patient fails to sweat, nor if he has a feeble heart.—*Hare: The Therapeutic Gazette.*

Oil of Wintergreen in Gynecology.

At a meeting of the Paris Obstetrical and Gynecological Society, M. Jouin reported that he had treated metritis and its various complications, but more particularly gonorrheal endotrachelitis, by means of applications of oil of wintergreen, and with success. He stated that in some cases the medicament has found its way into the Fallopian tubes, and cured old cases of salpingitis.—*N. Y. Med. Jour.*

Medicolegal.

Sixty-Four Years Makes an Old Man.—Without any discussion of what may be said to constitute an old man, or when one becomes such, the Supreme Court of Mississippi holds, in the case of Bertram vs. The People's Railway Company, that a man 64 years of age was manifestly an old man.

Not Questions for Medical Experts.—A few cases seem to support asking medical experts, in prosecutions for rape, such questions as whether that crime can be committed upon an ordinary, mature female. But the Supreme Court of Iowa says that the better opinion appears to be the other way, for the reasons: First, that to permit such evidence would allow the witness to assume the functions of the jury; and, second, the matter inquired about is not the subject of expert evidence. Wherefore, it holds, in State vs. Petersen, that an objection to a question of this character was properly sustained, as also objections to questions propounded to medical experts, based on facts that the evidence tended to prove, calling for an opinion as to whether or not it was possible for the defendant to have had intercourse with the prosecutrix, a German girl 15 years of age, against her will and objection.

Sale of Intoxicating Liquor in Compounds.—Under the law, the Supreme Court of Iowa says, in the case of State vs. Gregory, a registered pharmacist has a right to compound and sell drugs and medicines, even though they contain intoxicating liquor. But where, as in that state, he is not allowed to sell any preparation or compound, intoxicating in character, that might be used as a beverage whether or not a compound is such that a sale thereof is inhibited is not a question of law, but of fact for the jury. And, in a prosecution for keeping a liquor nuisance, or an unlawful sale of intoxicating liquor, the test would seem to be, and the court holds that the jury should be instructed, that, if the liquor sold was so compounded with other substances as to lose its distinctive character as an intoxicant, and no longer desirable for use as a stimulating beverage, and was in fact a medicine, then the sale of it by a registered pharmacist did not violate the law.

Authorized Disclosures in Murder Cases.—Section 834 of the New York Code of Civil Procedure, which provides that "a person duly authorized to practice physic or surgery shall not be allowed to disclose any information which he acquired in attending a patient," etc., was enacted for the protection of the patient, and to enable him to make known his condition to the physician without danger of any disclosure by him. In a case to which this section of the code is applicable, the privilege can not be waived by any one save the patient, and, if he be dead, the seal of the statute can not be removed. But Mr. Justice Hooker, who made these statements at a special term of the Supreme Court of New York, goes on to say, in People vs. Benham, that the aid of this section can not be invoked to shield a person charged with the murder of the patient. And, such declarations and confidential communications from the patient to the physician being admissible under this statute, when they tend to prove the crime of murder, he holds that they are none the less admissible when they tend to disprove it.

Impulses, Delusions, and Proof of Insanity.—The doctrine of irresistible impulse, which has been upheld by some supreme courts, the Court of Criminal Appeals of Texas disavows. It maintains, in Cannon vs. State, that, if a person has an irresistible impulse to commit a crime, and does not know the nature and quality of the act, he is insane. If he does know right from wrong, and knows the act to be wrong, he is not insane. Likewise, the court holds that there is no grade of delusion that mitigates crime. In other words, a party can not be half insane. If at the time he kills another he is laboring under a delusion, and such delusion deprives him of his capacity to know right from wrong, he is insane. Moreover, general reputation of insanity, the court holds, can not be proved. Nor does it consider that the sanity or insanity of a defendant's wife can throw any light upon his mental status. And because it is convinced that drugs and narcotics may have a more injurious effect upon the mental condition of one person than they do upon that of another, it holds that it is not admissible to show that one person was insane simply from the use of such drugs. Not only does it consider that this would certainly be the rule where there was no proof as to the relative physical resistance of the different parties using the drugs as to the effect of such drugs, but that it would also be the case even if the proof showed that they used the same amount of drugs for the same length of time, as it would be true where there was no proof that they used the same amount of drugs or for the same length of time.

Mental Injury Amounting to Total Disability.—In the JOURNAL of May 12, 1900, on page 1181, were given the views which the Court of Civil Appeals of Texas arrived at on this subject on a rehearing which it granted in the case of the Fidelity & Casualty Company vs. Getzendanner. As there stated, the court decided that it had erred in condemning, on the first hearing, a charge which had been given to the jury with regard to what mental injury would amount to a total disability under a policy of insurance against accidents to the person which should "wholly disable and prevent the assured from performing any and every kind of duty pertaining to his occupation." But after its first decision was rendered, and apparently before it had time to reverse itself, the Supreme Court of Texas was called upon, through the medium of a certificate of dissent, to give its opinion upon the charge in question. Whether or not it was in the meantime advised of the effect of the rehearing does not appear, but regardless of the fact that the court of civil appeals considered that it had made a mistake in the first instance in condemning the charge, the supreme court now holds that it was right in condemning it. The supreme court does not enter into any particular discussion of the general subject. It believes that the great weight of authority is against holding to a literal construction of such language as that used in this contract. At the same time, to say that one who is disabled by an injury is wholly disabled to do anything, merely because he can not do it "in a manner reasonably as effective as the same would have been performed if the injury had not been sustained," it declares seems to it a solecism in language, if it does not involve a contradiction in terms. And as that is what it considers was the practical effect of the charge in question, it holds that it involved a technical error, as it could only be justified upon the theory that the slightest impairment of the mental faculties wholly disables one who is engaged in buying and selling, for example, from pursuing his avocation, whereas such is not the fact, because there are infinite gradations in mental deterioration, and it is a matter of common knowledge that persons with some degree of cerebral disturbance may continue to prosecute with reasonable efficiency a business which requires the exercise of judgment and discretion. As well, it seems to think, say that a carpenter with a sprained finger is totally disabled, if it be that he can not pursue his calling as effectively as if he had not received the injury, although he may be able to do, without serious inconvenience, 90 per cent. as much work as he could have done before the accident happened.

Physical Examinations in Federal Courts.—It is settled in the Supreme Court of the United States, as the latter declares, that no power exists at common law to order a surgical examination of the plaintiff in an action to recover damages for injury to the person; in other words, that the court has no inherent power to make an order for such an examination in such a case. This rule, too, it expects to be followed in United States courts sitting in states where no statute has been passed providing otherwise, but in which it has been held that the court has inherent power to order the examination of a plaintiff in this class of action without the aid of a statute. And this, notwithstanding that section 721 of the Revised Statutes of the United States provides that "the laws of the several states, except where the constitution, treaties, or statutes of the United States otherwise require or provide, shall be regarded as rules of decision in trials at common law in courts of the United States, in cases in which they apply." But where a state has a statute which provides for the making of an order for the examination of the person of the plaintiff in such a case, the supreme court now holds, in Camden & Suburban Railway Company vs. Stetson, the section just quoted applies that statute to cases of such a nature on trial in federal courts sitting in that state. Nor does it consider that the citizenship of the plaintiff at the time of the injury is material so long as the court below has jurisdiction of the case and the parties at the time of the commencement of the action. Such a state statute, the one under consideration being the New Jersey act of May 12, 1896, it does not think violates the federal constitution. The statute, it says, concerns the evidence which may be given on a trial in the state, and, it further holds, does not conflict with any statute of the United States upon that subject. It is not a question of a general nature, like the law merchant, but simply one concerning evidence based upon a local statute applicable to actions brought within the state to recover damages for injury to the person. Hence, the statute comes with the principle of the decisions of this court holding a law of the state of such a nature binding upon federal courts sitting within the state.

On Vaccination and Revaccination.—Section 23 of chapter 214 of the North Carolina laws of 1893 contains, among other provisions, this clause: "The authorities of any city or town, or the board of county commissioners of any county may make such regulations and provisions for the vaccination of its inhabitants under the direction of the local or county board of health or a committee chosen for the purpose, and impose such penalties as they may deem necessary to protect the public health." This, the Supreme Court of North Carolina holds constitutional, being, as it pronounces it, in the case of State vs. Hay, an exercise of that governmental police power to legislate for the public welfare, which is inherent in the general assembly, except when restrained by some express constitutional provision. It calls it but everyday common sense that, if a people can draft or conscript its citizens to defend its borders from invasion, it can protect itself from pestilence by such measures as medical science has found the most efficacious for that purpose. If, in the days of imperfect communication, smallpox often destroyed a third or more of the population of a country which it attacked, and so futile was every other precaution and the most careful seclusion that the greatest sovereigns fell victims to it. the court points out that the present rapid means of intercourse between the most distant points would so spread the disease as to quickly paralyze commerce and all public business, if the government could not at once stamp it out by compelling all alike, for the public good as much as for their own, to submit to vaccination. True. there are those who, notwithstanding the well-ascertained statistical facts with regard to the protection afforded by vaccination, deny the efficacy thereof, as there are always some who will deny any other result of human experience, however well established. But the legislature, acting in its best judgment for the public welfare upon the information before it, having deemed vaccination necessary for public protection, its decision, being within the scope of its functions, must stand until repealed by the same power. The power of the legislature to authorize county and municipal authorities to require compulsory vaccination, has been exercised by nearly every state, and there are no decisions against it. And the court goes on to say that even if it were of opinion with the small number of medical men who contend that vaccination is dangerous to health, and not a preventive of the disease; the court is not a paternal despotism, gifted with infallible wisdom, whose function is to correct the errors and mistakes of the legislature. Taking up the construction of section 23 before mentioned, the court holds that it does not require that the board of aldermen of a city shall pass the ordinance authorized in conjunction with the board of health. It holds that it merely provides that the execution of the ordinance—i. e. the vaccination—shall be under the direction of the local board of health, or a committee appointed by the aldermen. And it holds a valid exercise of the power conferred the passage of an ordinance, on the 13th of the month, that all citizens of the city "not successfully vaccinated within the last three years" should be vaccinated between that date and the night of the 17th, and that all persons refusing to be vaccinated should be fined $10 for every day they refused after being called upon by the doctor appointed, or imprisoned for 30 days. It says that it is true that there may be some conditions of a person's health when it would be unsafe to submit to vaccination, and which, therefore, would be a sufficient excuse for noncompliance; but, it holds, it does not vitiate the ordinance that such exception is not provided for and specified therein. It is not a defense that a person *bona fide* believes that it will be dangerous for him to be vaccinated, or believes that he is already sufficiently protected by former vaccination. Nor, the court further states, would the opinion of his personal physician on either point be conclusive (though it would naturally have weight with the jury), for there might be evidence or circumstances tending to the contrary. Indeed, as to a former vaccination being sufficient protection, the court holds that the opinion of the official physician supervising the vaccination should be presumptively correct. Finally, that which would relieve from a compliance with the ordinance, it holds, is a matter of defense, the burden of which is upon the defendant, and is a fact to be found by the jury.

SATURDAY, JULY 14, 1900.

PYREXIA AND ANTIPYRESIS.

There was a time when the febrile process, as well as the inflammatory one, was considered a distinct morbid entity, with more or less constant and characteristic features; and, although we are not yet cognizant of the intimate nature of the reactions that take place under such conditions, it is appreciated that they are due to the operation of a number of factors of varying kind and degree; so that the resulting phenomena may be correspondingly variable. It has further been maintained, as Liebermeister[1] points out in a philosophic communication on the subject of antipyresis, that the course of the febrile process should not be interfered with, but that it should rather be supported. It has, however, been learned more recently that while there are some conditions in which this precept is a good one to follow, there are others in which it is advisable to control the fever.

It was at one time thought that the febrile process represented a curative effort on the part of Nature, and antipyresis was, therefore, believed to be contraindicated; and, even now, fever is conceded to be a factor in the process of recovery, although when necessary, steps should be taken to mitigate its severity. Cold water has been employed on a larger or smaller scale for more than one hundred years, but it is only within the past forty that it has received at all systematic application. If it be granted that the febrile process exerts a conservative effect, it should not be forgotten that it is also capable of harm.

The dangers of fever depend in part on the fact that the total bodily metabolism is increased, while in consequence of impairment of appetite and of digestion, nutritional compensation is rendered more difficult; therefore, fever of any considerable degree is attended with loss of flesh, and long-continued, chronic fever may result in marked emaciation. In acute febrile diseases, and when the fever is high, there is also danger from the elevation of temperature itself. The human organism and all of its functions are adjusted for a temperature of 98.6 F., and any considerable deviation from this must have a bad effect on both structure and function, as manifested especially in parenchymatous degeneration when the temperature remains persistently high.

All tissues exhibit, during the existence of fever, a tendency to degeneration; so that mechanical or chemical influences that occasion little or no harm in the healthy body induce most serious changes, or even necrosis or gangrene. Wounds and ulcers show no tendency to heal while fever is present, but rather a disposition to extend. The functions of vital organs, as the heart and the brain, are interfered with by high bodily temperature. Cardiac weakness gradually develops in the presence of persistent high fever, and paralysis of the heart is one of the most common intimate causes of death under such circumstances.

On the other hand, as has been already stated, the febrile process is attended with increased metabolism, and this is antagonistic to the invasion of micro-organisms, and probably also inimical to their presence. It may be concluded that combustion of the bacterial toxins is, at the same time, hastened by general increase in oxidation processes. The indication for the physician is, therefore, to inhibit the deleterious effects of fever, without interfering with its beneficial effects. Practical have outstripped theoretical considerations in this connection, and, for a long time, abstraction of heat has been resorted to for the relief of severe febrile disorders, and when the treatment has been judiciously carried out, the results have entirely justified the practice. It may be admitted that the febrile process need not be attacked in every case, but only when it is attended with or threatens danger.

When abstraction of heat is desired, the full bath is the most efficient agent, and this may be, in accordance with the nature of the disease and of the patient, tepid, cool, or cold. During the cold bath, while heat-dissipation is increased and the temperature of the surface is lowered, heat-production also is increased, and the temperature of the interior of the body is perhaps raised, although subsequently the internal temperature also declines. Thus, by repetition of the bath, sufficient reduction in temperature can be effected to avert danger from this source, while at the same time the curative effect of the febrile process is not prevented, in so far as this depends on increased metabolism. Respiration becomes deeper, the action of the heart strengthened, the mind clearer, appetite and digestion improved, the patient feels refreshed and recuperative sleep is favored. Perhaps, also, toxins present are destroyed as a result of increased oxidation-processes. In order not to lose the good effect of the febrile process, it is Liebermeister's practice not to interfere, as a rule, with the fever during the day, unless it be excessive, and to give a sufficient number of baths during the night to bring about a satisfactory remission. The danger of high fever resides especially in its continuousness, and the plan mentioned overcomes this.

Hyperpyrexia may, however, be more conveniently reduced by the use of antipyretic drugs; but the results from the use of such remedies exclusively have been by no means good, because, even if no toxic effect is induced, the useful influence of the f[illegible]s is al[illegible] removed with the reduction in [illegible] retics may, however, be advantageously employed in cases in which the baths appear incapable of inducing remission in the fever, or in which they are contraindicated for one reason or another. The object to be attained, however, is not an entire suppression of the febrile process, but rather the induction of adequate remissions from time to time.

THE RELATION BETWEEN PATHOLOGY AND THERAPEUTICS.

Intelligent and successful treatment—prophylactic, curative, paliative—obviously demands a proper knowledge of the causes and the processes of disease. It is imperative, for the judicious application of therapeutic measures, that one be able to discriminate normal from abnormal effects, as well as to appreciate those induced through the intervention of art. It may at times be helpful to aid the natural processes, not less than to check, or to divert them as occasion requires. The last two decades have witnessed a wonderful transformation in our conceptions of pathologic processes, and it will scarcely be contended that we have yet wholly emerged from the obscurity that naturally attends the evolution of a new phase of knowledge. The progress made in this department of medicine has in turn not been without a profound influence on what after all is the ultimate function of the true physician—the preservation of health, the prevention and the cure of disease, and the relief of suffering.

In a philosophic essay, delivered as the annual address before the Medical and Chirurgical Faculty of Maryland in 1896, Dr. S. Solis-Cohen[1] forcefully pointed out that health and disease are not entities or forces, but states of the organism. Health, he defined, as the condition in which the adjustment of internal relations to external relations is most readily maintained. Disturbance of internal relations constitutes disease, and this may result from failure of internal adjustments, from failure to react properly to changes in external relations, or from failure in the process of reaction and readjustment. Schleich describes disease as "a form of the struggle for existence against those injurious influences to which man is not yet adapted," while, according to Hueppe, disease may be looked upon as an endless chain, from which, if any link be missing, the closing of the chain is impossible, and disease can not occur. Cohen further maintains that disease and recovery are alike vital processes, sometimes one continuous process, in which the organism itself is the most active agent. Neither the agents provocative of disease nor the agents used in treatment impart to the organism new qualities, or introduce into its operations new powers. They may modify that which is habitual, or they may evoke that which is latent. The power of the human body to return to health comes from within, and not from without, as a natural endowment, and not as a gift of art.

In a thoughtful paper read recently before the Practitioners' Society of New York, Dr. T. Mitchell Prudden[2] points out that the practitioner, after all, is ever a pathologist, his clinical observations being really studies in pathologic physiology, At an earlier period the most distinctive function of the physician-pathologist was the making of autopsies and the naming of tumors. Later, as the work of the pathologist became more thoroughly specialized, his most obvious aim was to discover some new lesion, or to give greater precision to the morphology of an old one; to gather statistics; to exploit organs of exaggerated size; and in general to celebrate the monstrous and the strange. Description and classification became the business of the hour. As time went on, the cell was no longer looked upon as a mass of living matter of simple chemical composition, but as a most complex mechanism with varied structural features, while the nucleus contained the special structures closely involved in reproduction and heredity and the processes of cell-nutrition.

In the evolution of our conceptions of the causes and nature of the infectious diseases it has become clear that disease is a process resulting from the action of the living body-cells, on the one hand, and specific inciting factors on the other. Disease and health are not things, but processes, essentially transformations of energy, differing in accordance with the differences in the conditions under which the forces are brought into play. The normal processes represent the results of the conditions under which the cells have been slowly evolved, and at the time placed; while the abnormal processes involve no new forces, but represent a modification by new conditions of the manifestations of energy of the normal state. The resultant lesions, however, do not constitute the disease. The cause of physiologic performances is the potential energy, or capacity for work inherent in the organism, and the true causes of disease are the same dynamic conditions acting under modified circumstances. The manifestations of the infectious diseases are expressions of processes of the body-cells, and not of the invading micro-organisms, which afford only one of the necessary conditions.

With regard to immunity and tolerance, and health and disease, Prudden points out that the life of the cells of the body, like the life of microbes, is a continuous adjustment between the properties of the organism and those of its environment, that the nice balance of health may be swayed by innumerable agencies from within the body and from without,and that the body-cells,as well as the bacteria, are organisms capable of considerable variation, in both form and function, when the conditions of their existence change. Natural or acquired cell-tolerance to poisons may be, and often is, a matter of cell-education, although it can not be denied that there is such a thing as specific immunity. Inflammation, as suggested by Adami, may be looked on as a series of changes constituting the local manifestations of the attempt at repair of injury, while the solution of the etiology of the new-growths must be deferred until we know more of cytology in general.

[2] Medical Record, March 10, 1900, p. 397.

THE ATAXIC VARIETY OF ALCOHOLIC MULTIPLE NEURITIS—SO-CALLED PERIPHERAL NEUROTABES.

The recognition of multiple neuritis as a distinct morbid entity dates back only twenty years, when the clinical and anatomic characters of the disorder were first fully pointed out by Leyden. Previously the symptoms had been attributed to lesions of the spinal cord; but in the small number of cases in which post-mortem examination could be made these alterations were not found. It has since been learned that polyneuritis may result from traumatic influences, in the course of infectious diseases, and from the action of various poisons. Exposure to cold acts probably as a contributory factor, merely lowering vitality and thus favoring the invasion of micro-organisms.

Chronic alcoholism is probably the most important etiologic factor, and under such circumstances the disorder has been observed to appear in three forms, in which motor, sensory and ataxic symptoms have respectively predominated. The motor, or paralytic, or amyotrophic variety is by far the most common; the ataxic is much less so; and the sensory variety is quite rare. In the ataxic cases the inco-ordination may be present in the upper or the lower, or in all four extremities; and the motor and sensory symptoms are wholly subordinate. The disorder often develops with violence, in the course of several weeks, in a person previously well, when static and motor ataxia will be found to be present, with abolition of the knee-jerks, while the reflex activity of the pupils is preserved. Other symptoms of tabes dorsalis have also been observed, as, for instance, a girdle-sensation, vesical disturbance, amblyopia, diplopia. Also alterations in the electric reactions of the muscles and nerves: enfeebled response to the faradic current, or complete or partial degenerative reaction, have been noted. Sensory changes are slight or wanting, and when present affect especially the localizing sense. Irritative phenomena, in the form of spasm, may also attend polyneuritis.

An interesting case illustrating many of the foregoing points is recorded by Hőnig.[1] The patient was a butcher, 55 years old, without neuropathic predisposition, but with a history of syphilis and alcoholic excess, in whom, in the course of four weeks, weakness appeared in the lower extremities, then extending to the upper extremities, with various paresthesiæ, and painful spasms in the muscles of the fingers. The most conspicuous symptom was ataxia, which appeared on standing and walking, and was marked on spontaneous movement of the upper and lower extremities. There was scarcely any sensory disturbance, and this involved only the power of localization. There was, however, marked atrophy, especially of the thenar muscles, with partial reaction of degeneration. The plantar reflexes and the knee-jerks were abolished, but the pupilary and the remaining reflexes were preserved. The functions of the rectum and the bladder were unaffected. The use of alcohol was strictly interdicted, and the patient was treated with daily baths at a temperature of 82.4 F., faradization, and strychnin, and marked improvement progressively took place. The ataxia disappeared; the absent reflexes returned; sensibility and the electric reactions became normal; and almost all of the previous symptoms subsided, only slight stiffness without pain persisting in some of the fingers of one hand, but even these eventually disappeared.

In an analytic consideration of this case and of the related literature, Hőnig points out that in a not inconsiderable number of cases of alcoholic multiple neuritis, changes of varying degree and extent have been found in the spinal cord and in the brain, in addition to those in the peripheral nerves. In view of this fact, and of the further fact that in some cases spinal and cerebral symptoms are present, such as the muscular spasm in the present case, and psychic disturbances and ataxia, the conclusion is expressed that neurotabes can no longer be considered a disease purely of the peripheral nerves, but, as the evidence shows, may also involve the spinal cord, and probably also the cerebrum, and particularly its cortical structure.

THE SAN FRANCISCO PLAGUE SITUATION.

Now that some of the San Francisco papers are demanding that an example, so to speak, be made of Dr. Kinyoun for the part he took in regard to the plague in that city, it may be well to notice some of the facts in the case. From March 6, the date of the first case identified until quite recently, the weight of medical testimony has been in favor of the existence of sporadic cases of plague in San Francisco, the chief seaport gate to the Orient on the Pacific coast. There is nothing remarkable in the fact that the diseae should appear there, for the city has been in constant danger from China and Japan, and there is not much more reason to suppose it would escape than Honolulu or Manila, which were infected from these sources. San Francisco contains, moreover, a large Oriental population, living in most unsanitary conditions and affording an excellent bed for the pestilence when it came. The San Francisco health officials felt their responsibility and acted accordingly, and the abuse they have received from mercenary commercialism is the strongest evidence that can be afforded that they attempted to do their duty. The cleansing and quarantining of the Chinese quarter was of course offensive to the Chinese, and the reputation of being a plague-infectd city was disastrous to the business interests, hence the attacks upon the health officials in the newspapers, which have assumed and insisted for business reasons, that there has been no plague whatever in the city. Finally legal proceedings were brought against the health board and quarantine officers at the instance of the Chinese consul and the Six Companies that control the Chinese, and the quarantine of Chinatown was abolished by a judge who is said to have expressed his personal opinion with his judicial decision that no plague had ever existed. The mercantile interests called in to their aid the politicians and the governor of the state, who insisted that the medical authorities were all wrong and that plague did not exist and had not existed. Finally Dr. Kinyoun was arraigned for contempt of court, though this has come to nothing. A New York physician was sent by a syndicate of newspapers to investigate the matter, and while he did not condemn the health officers, he has certainly been unlucky in the published interviews and statements credited to him by the local press. Some local physicians have also committed themselves strongly against the health board and the United States medical officers in a way that appears to us to be most unfortunate, considering all the facts. If the health officers had slighted their duty and the disease had obtained a foothold through their neglect, no condemnation would seem too severe to those who are now blaming them for what they did. If they have failed to do enough, on account of the embarrassments under which they worked, the penalty will be upon their detractors, who will then recognize their error and see that newspaper dicta, judicial opinions or gubernatorial utterances have no more effect on a pestilence than Mrs. Partington's broom on the flood. On the other hand, if the energetic measures they instituted have been sufficient to stamp out the disease, they deserve public gratitude—which they will not receive—the appreciation of their efforts will depend upon their failure.

---

[1] Deutsches Archiv f. Klin. Med., Bd. lxvii, H. 1 u 2, p. 163.

The situation is not a satisfactory one, but it is the best that can be expected under present circumstances, and they will at any event have the reward of a clear conscience in the matter. It is far from certain that their vindication will not come, the possibilities are all still ahead and the future may show a worse condition of affairs than has yet existed. The matter is one that interests the whole country; if plague gains a foothold in a Pacific port, the danger is one common to us all, and it is not to our advantage to be supine and allow Chinese companies and trading interests to let loose a pestilence upon us. It would not be surprising to those who know the natural history of the disease if it should suddenly break out again with great virulence. While it is hoped that events will prove that there is no cause for further alarm, still it might be well, even from a financial point of view, to remember that the time has not yet arrived for the rendering of the final verdict. The experience of other cities has been that sporadic plague one year has often been the precursor of an epidemic the year following. We trust this will not be the case in San Francisco.

In this connection we call attention to the report by Dr. Montgomery, which appears elsewhere in this issue, in which he reviews the facts in the case.

THE ALCOHOL QUESTION.

Professor Hall's paper in this issue is a contribution to a subject that has at present a special adventitious importance. The food value of alcohol is insignificant at best, if it can be assumed to exist, but recent utterances on the subject have been so utilized by interested parties, far beyond any desire of their authors, that corrective articles like that of Dr. Hall and that of Drs. Woodbury and Egbert in a former issue of The Journal are timely and valuable. It is not desirable that any truth should be misrepresented or suppressed, but a suggestion of caution as to statements that can be possibly perverted or distorted, such as those that can be construed to favor alcoholic indulgence, will never be much out of place. The experience of some who have been unguarded in this respect can hardly be considered desirable.

TUBERCLE BACILLI IN THE BREAST MILK OF A TUBERCULAR WOMAN.

We know that in the bovine species tubercle bacilli may appear in the milk of tuberculous females, even though there is no tuberculosis of the udder. The literature does not contain any report of the presence of tubercle bacilli in the milk of nursing mothers having been demonstrated by animal experiments previous to the case recently described by Roger and Garnir.[1] The woman was 34 years old and died from advanced pulmonary tuberculosis, with miliary nodules in other organs, two weeks after giving birth to a child, which nursed its mother's breasts for a few days, dying from generalized tuberculosis when six weeks old. Subcutaneous injection of a guinea-pig with 4 c.c. of the breast-milk caused the death of the animal after five weeks; here was a typical general inoculation tuberculosis. Clinically there was no evidence of tuberculous infection of the mammary glands of the mother. Anatomically this point does not seem to have been investigated. Further observations are consequently necessary before it may be stated positively that bacilli may pass into the milk without local tuberculous lesions of the breasts. This case points in this direction, and the inference is supported by the positive demonstration of bacilli in cow's milk without disease of the udder.

THE ANNUAL CASUALTY DAY.

The Fourth of July has passed with its usual record of casualties and it becomes necessary to say our annual word in regard to them. There is a phase of the popular idiocy of the day that has not received the attention it deserves, yet it is a psychologic factor of great influence in the often unfortunate outcomes. It is not mere noise, that the average boy or hobbledehoy enjoys; it is the zest of risk and the notion that there is something manly in playing with gunpowder and firearms on this day of license. If it were not for this, half the interest would be gone—we can testify to this, since, as the saying goes, we have been there ourselves. The younger the child, the easier is this gratified, the firecracker burns on the fingers and the holes in the clothes are shown with pride. With the older child the gas-pipe cannon and the giant cracker get in their work, or the pistol or old musket finds its victim. There is hardly an average citizen who has not had personal knowledge or experience of some unreported minor casualty of the Fourth and there is no one of ripened years and judgment who does not deprecate the costly and foolish performances that he probably enjoyed in his immaturity. As medical men we have double reason to appreciate the idiocy of the performance, and would hardly be doing our duty did we neglect the occasion to condemn it. The man who will invent and popularize a more rational way of celebrating our national holiday will deserve to rank with those who founded it, as the savior of a very large contingent of his countrymen.

HEMORRHAGIC NEPHRITIS THE EXPRESSION OF GENERAL INFECTION.

Instructive cases have been described recently by Holst[1] of acute hemorrhagic nephritis as the principal manifestation of a general microbic infection of the blood. In one case the disease lasted nearly eight months and was in reality a streptococcus bacteriemia—streptococci being found in the blood and elsewhere—but appeared clinically as a hemorrhagic nephritis of a febrile type. In the second case, the renal symptoms were associated with evidences of acute endocarditis. Staphylococcus albus was grown from the blood during life, and after death from the excrescences upon the mitral valve. A third case was observed for a time. Here there existed a fully-compensated heart lesion of some duration, but which rather suddenly became complicated with symptoms of acute nephritis. While under observation, the urine, secured under aseptic conditions, contained micrococcal masses that proved to be staphylococcus albus in pure culture. Holst emphasizes especially these two points: 1. Acute hemorrhagic nephritis represents a bacteriemia—latent pyemia or septicopyemia—more frequently than is commonly believed. 2. Transitory hemorrhagic exacerbations occurring in the course of chronic nephritis may be caused by an infection of the blood, just as is frequently the case in recrudescence of endocardial inflammations, the recurring hemorrhagic nephritis being similar pathogenically to recurring endocarditis.

URETERAL IMPLANTATION.

Many pathologic conditions offer indications for implantation of the ureters into the rectum or colon. As examples may be mentioned uretero-vaginal fistula; stricture and obliteration of the ureters under conditions preventing reinsertion of the ureter into the bladder; large vesico-vaginal fistulæ; tuberculosis and carcinoma of the bladder; and atrophy of the bladder. In these and other conditions, new routes for the discharge of the urine are desirable. Turning the urine into the rectum is not altogether against all physiologic precedent. In birds, for instance, there is a common route of exit for both urine and feces, and cases have been recorded in which the ureters emptied into the rectum in human beings, by virtue of the persistence of an early embryonic condition. Richardson's patient lived seventeen years, and *without urinary incontinence*. We have also learned that the rectum may acquire tolerance of the presence of urine. It is the occurrence of ascending infection of the urinary tract that constitutes the most serious obstacle to uretero-colostomy. The only method that, so far, successfully overcomes this danger is Maydl's, whereby the part of the urinary bladder containing the ureteral orifices is properly fixed in the intestinal wall. The preservation of the normal ureteral openings is the reason why Maydl's method is superior to all other procedures yet devised. In all other operations, even when the ureters are inserted obliquely and the orifices guarded by an ingeniously constructed valve of rectal mucous membrane, there is, sooner or later, retraction, atrophy of the valve, and infection. Inasmuch as Maydl's method of ureteral transplantation is not always applicable, a method of creating an orifice in uretero-colostomy that does not retract is a desideratum, which surgical ingenuity has yet to furnish.

THE ETIOLOGY OF PERTUSSIS AND ITS SERUM TREATMENT.

In the recently issued and splendid volume, entitled "Contributions from the William Pepper Laboratory of Clinical Medicine," occurs an article by Joseph Walsh on the etiology of whooping-cough. He notes that the number of organisms discovered in this disease is quite remarkable—a new organism has been found for every alternate year of the last two decades. Protozoa, cocci, and bacilli have been described. Two bacilli have received especial notice: The one described by Afanassiev, whose finding was confirmed by Koplik of New York, and the bacillus of Czaplewski-Hensel. Walsh studied twelve cases and made one autopsy, isolating the Czaplewski-Hensel bacillus from the sputum seven times and finding the same organism in smears from the sputum of nine cases and from the trachea at the postmortem. On carefully reviewing the characteristics of this bacillus, Walsh is forced to the belief that it is a so-called pseudo-diphtheria bacillus. It is not necessary to recount the cultural and other properties that identify the bacillus with the pseudo-diphtheria group. This identity makes it hard to prove that the bacillus is the actual cause of whooping-cough, because similar forms are often present in the healthy throat. Its presence in overwhelming numbers in so many cases of pertussis, even in the washed sputum, and on the tracheal lining after death, makes it probable, however, that it is the exciting cause of the disease. It seems that Koplik has changed his opinion to the effect that he also dealt with the Czaplewski-Hensel bacillus (Walsh). On account of the almost perfect immunity granted by an attack of whooping-cough, Walsh thought that the serum of persons who have passed through an attack might contain an antitoxin. A few injections of human serum were given patients with pertussis, and all injected showed immediate and marked improvement, with complete cessation of the whoop for two or three days, after which it returned, except in one case, the first to be injected, in which it never returned. The results obtained seem to indicate further trials in this direction.

---

[1] Norsk. Magaz. f. Lagevid., 1899.

Medical News.

Reaumur thermometers are no longer to be officially tested in Germany as heretofore. The Centigrade is henceforth the only standard thermometer for the Empire.

Victims of alcoholism in the Russian Army are to be treated in a special hospital, the funds for the erection of which have been contributed by the Russian government.

Medical promenades at the Exposition, to point out and describe articles of special interest to visiting physicians, have been organized by Drs. Helm and Marcel Baudouin.

An institute for medical diagnosis has been inaugurated in Berlin, in which various specialists, such as Klemperer, Posner, Eulenberg, etc., hold clinics of an hour each during the day.

All surgeons, assistant-surgeons, acting assistant-surgeons or contract surgeons, and hospital stewards, who served in the army or navy of the late Confederate States, are requested to send their post-office addresses to Deering J. Roberts, M.D., Secretary Surgeons' Association, C. S. A., Nashville, Tenn.

The Medical Club of Paris offers temporary membership to visiting physicians at its handsome quarters, 5 Avenue de l'Opéra, with all the privileges of club life, large dining-halls and dinner at 7 p. m., with concerts and dramatic entertainments from time to time. The fee for temporary membership is ten francs, or $2.

The Duchy of Meiningen in Germany has extended the system of medical school inspection to the rural as well as to the city schools. After the current year, only the children entering school for the first time will be examined, with further examination when they leave school or at the request of teachers. The service is free and will be extended to private schools on demand. Much good is anticipated from the advice to be given to boys leaving school as to their physical fitness for certain trades.

On the initiative of the medical profession in the Bordeaux district, France, a statue has recently been erected to the memory of Dr. Jean Hameau (1779-1851) in the remote village where he lived and died. In a pamphlet entitled the "Study of Viruses," which lay unnoticed in the pigeon-holes at the Académie de Médecine for seven years, and was then only vaguely comprehended, Hameau outlined the theory of parasitic infectious diseases which was confirmed later and rendered intelligible by Pasteur's discoveries.

The new German law for the prevention of contagious diseases aims at the compulsory isolation of every person affected, or even suspected of being affected with leprosy, cholera, petechial typhus, yellow fever, plague and smallpox. The physician is required under penalty to notify the authorities. When the sanitary officials are prevented from attending to the duties imposed by this law civilian physicians are compelled to act in their stead. Severe penalties are imposed for knowingly passing over to a third party any articles that have been used by or for a patient affected with any of the above diseases. An indemnity is paid by the government for articles destroyed in disinfecting. The law does not conflict with the regulations now in vogue for other transmissible diseases.

Sanitary Telephoning.—Telephone booths in Vienna are furnished with napkins, and those who telephone are requested to wipe the mouthpiece of the transmitter. If the napkins are changed often enough and the telephone users are careful to observe the instructions; the mouthpiece should be kept in fair sanitary condition.

Trichinae in German Pork.—A Nuremburg paper, commenting on the fact that eleven out of thirteen trichinous pigs, found in the city market during the last year, were all of Prussian lineage, concludes that the policy of excluding meat from the United States is foolish and that careful inspection is the only safeguard.

The Health of Manila.—Major Edie's recent report shows that the health of Manila compares favorably with that of other oriental cities. The death-rate from October to June was 28 per thousand. The total number of deaths was 8535, of which 180 were caused by the plague, and 1073 by internal diseases. This report demonstrates that the sanitary condition has materially improved.

Asepsis in Churches.—The Roman Catholic bishops in Italy are instructing their clergy to sweep and disinfect the floors of churches with sublimate at least once a week, and after each crowded service. The receptacles for holy water and other articles are to be frequently cleaned with boiling water or sublimate. The *Semaine Médicale* urges the generalization of these measures as a great benefit to the health of the public, if systematically applied.

ANOTHER CASE OF PLAGUE.

(Special Telegram to The Journal.)

San Francisco, California, July 10.—A Chinese laborer, aged 40, was sent to the City and County Hospital, July 4. He had been perfectly well until one week before. He felt tired and depressed; had fever and drank large quantities of water. He was confined to his bed for two days and was then carried to the hospital his temperature was 104 F.; pulse, 120; respiration 36. The abdomen was much distended and tender on pressure, and the spleen greatly enlarged. The bowel passages were blood-stained. A large bubo, the size of the fist, was seen in the left inguinal region, but he had no urethral discharge. The urine gave no diazo reaction. After his entrance to the hospital, dyspnea developed and he lay in a semi-conscious condition, and was delirious until his death, which occurred July 6, at 6:30 a. m. On autopsy the mucous membrane of the intestines was found to be thinner than normal; the solitary follicles normal; there was hyperemia of the heart, swelling of the axillary and inguinal glands, and infectious swelling of the spleen. Bloody fluid was found in the pericardium. A guinea-pig that was inoculated with fluid aspirated from the bubo on the day before the patient's death died sixty hours after the inoculation. The autopsy revealed widespread edema of the subcutaneous tissue, with coagulation-necrosis at the site of the inoculation. The pleural and peritoneal cavities contained turbid bloody fluid. The blood in the heart was fluid and the heart muscle dark and friable. The spleen was three times its normal size and contained yellowish-white spots, which were colonies of the bacillus pestis. The plague bacillus was found in the blood, in the inoculation wound, and in the spleen. Cultures made from the fluid aspirated from the patient before death showed the plague bacillus. This is the first case of bubonic plague in San Francisco in which the diagnosis was made before death. Many animals were inoculated from the fluid aspirated from the bubo, and interesting results from these inoculations may be expected.

[This telegram was received after the editorial on this subject had gone to press. ED.]

PENNSYLVANIA.

DR. F. E. JENKINS, of Carbondale, has gone to San Francisco, from which place he will sail for Manila.

DR. HENRY ARMSTRONG, of Sharon, who has for some time been attending a case of smallpox near that place, is said to have contracted the disease, and the Board of Health has placed guards around his residence.

BOVINE TUBERCULOSIS.

Dr. Leonard Pearson, state veterinarian, announces that the following sums have been paid during the past year for the destruction of tuberculous cattle: Bradford County, $1242.50; Bucks County, $2663.50; Chester County, $4775.50; Dauphin County, 737; Erie County, $1412; Lancaster County, $1802.50; Montgomery County, $3737.50; Washington County, $1215. The total amount paid for this purpose over the whole state was $33,097.

COMPULSORY VACCINATION IN PENNSYLVANIA.

Judges Pennypacker and Sulzberger, in Common Pleas Court No. 2, during the first week of June, after hearing the argument on the petition of Charles J. Field for a writ of peremptory mandamus directed against Martha L. Robinson, principal of the Keystone Public School of Philadelphia, requiring her to admit to the school the daughter of the petitioner, Victoria Field, notwithstanding she has never been vaccinated, stated that the question at issue was whether after the legislature believed in the efficacy of vaccination, a citizen had the right to appeal to the court to say that such was notthe fact. Counsel for the defendant stated that he had collected every decision made in every state regarding this question, and that the practice of vaccination had no justification in science; that it did not mitigate smallpox, but often inflicted worse diseases, and for that reason was an abuse of the police power of the State to enforce this law. Attorney for the defendant attempted to prove that vaccination was without value, and cited as his authority the name of a physician in attendance at a municipal hospital (see JOURNAL of June 23, 1900—Philadelphia Letter), but which was contradicted by the physician named. The judges held the matter under advisement. On July 3 they overruled the demurrer and entered judgment for the defendant, Martha L. Robinson, principal of the Keystone School, who acted under the instructions of the law as outlined in the act of Assembly of June 18, 1895, thus making legal the enforcement of the compulsory vaccination law in the State of Pennsylvania. A similar opinion was given by the Supreme Court in 1894, on an appeal from a decision of Judge Metzger, of Lycoming County, who denied a writ of mandamus on the same grounds. In the latter case cost of the suit was imposed upon the appellant.

Philadelphia.

DR. MELVIN M. FRANKLIN has been appointed surgeon on the staff of St. Joseph's Hospital to succeed Dr. John S. Miller, resigned.

DR. JACOB M. DACOSTA tendered a complimentary dinner to a number of invited guests at his home near Villanova, June 29.

DR. JUDSON DALAND leaves for Europe July 15. He will attend the meeting of the British Medical Association and the International Medical Congress at Paris.

DR. JOSEPH LEIDY has been apppointed a member of the Jury on Hygiene from the United States, at the International Congress on Hygiene, which meets in Paris, August 4.

THE PUBLIC baths of the city have been well patronized during the past week, 416,220 persons having availed themselves of the opportunity thus afforded.

DURING THE past week a decision has been handed down in the case of Robert Nebinger, who died several years ago, in which the court allows the gift of $3000, made to St. Francis Hospital.

THREE PERSONS charged with violating the pure food law were arraigned in court during the past week, and held in bail of $400 each. Three other defendants failed to appear and steps will be taken to compel them to be present.

CONSIDERABLE excitement exists in the neighborhood of "Plaster Row" over the discovery of two cases of smallpox among the colored people. The patients have been taken to the Municipal Hospital, and about 200 of those exposed have been placed in quarantine, while eight policemen have been detailed to see that the quarantine is enforced.

MORTALITY STATISTICS.

The number of deaths occurring in this city during the past week was 544, an increase of 47 over that of last week, and an increase of 109 over the corresponding period of last year. The principal causes of death were: apoplexy, 22; cancer, 9; cholera infantum, 73; tuberculosis, 35; inflammation of the brain, 29; pneumonia, 27; marasmus, 30.

STERILIZED MILK AND ICE SOCIETY.

Through the work of this society an incalculable amount of good has been done during the past week for the relief of the children of the poor. This is the seventh year of the work of this society, and four depots have been established in the city for the distribution of these necessities. At all of these places the milk is carefully sterilized and sold at absolute cost to those who need it. A six-ounce bottle of milk together with a small piece of ice to keep it cool is usually the amount allotted to each applicant.

FOURTH OF JULY CASUALTIES.

Although the mayor had issued strict injunctions against the useless firing of toy pistols and other devices for making a noise during the celebration of the Fourth of July, that event has again been attended with several hundred injuries. As usual, lacerated wounds of the hands and face, injuries to the eye, and burns of the face and hands were most frequent. One colored boy fired into a collection of torpedoes, causing a wreck of the store and the death of eight people. The city is making an inquiry into this accident, as the storing of such explosives is forbidden by law. Friends of the Italian who owned the store at which the explosion occurred are said to have threatened death to any who would report the facts in the case.

NEW YORK.

DR. R. J. WILDING, of Malone, sailed last week for Europe.

DR. ALBERT SNELL, of Rochester, who has been in London for a year, has returned.

DR. F. HOLLET SPENCER, of Binghamton, has resigned the position as assistant physician and surgeon at the Robert Parker Hospital.

DR. ROBERT B. LAMB, of the staff at the Matteawan State Hospital, has been appointed medical superintendent of the Dannemora Hospital for the Insane.

THE NEW hospital established in Mineola, L. I., by the Nassau Hospital Association, was opened June 30. Addresses were made by Dr. James, of Manhattan, and Supt. C. Irving Fisher, of the Presbyterian Hospital.

AT A meeting of the Medical Board of Thrall Hospital, Middletown, Dr. W. C. Douglass was added to the consulting medical board, Drs. D. B. Hardenbergh and M. A. Stivers were elected to fill vacancies in the medical board, and Dr. W. I. Purdy was transferred from the medical to the surgical staff.

FINE FOR ILLEGAL PRACTICING.

The New York County Medical Association has
legal decision authorizing it to receive the fin
illegal practice of medicine. The law pro
the complainant in such cases is a state medi
county medical society entitled to representa
society, such fines shall be paid to the com
claimed by the city authorities that the act

LIBRARY,

the county medical society in affiliation with the state medical society, but the plea was overruled. Justice McAdam, in his decision, said: "The construction of the statute contended for by the defendant would not effectively carry out the provisions of the act in regard to prosecuting offenders, for this is more surely accomplished by the liberal construction now given to it. The plaintiff discovered the offender, secured his conviction; the fine represents the fruit of its efforts, and there is no reason why it should not have the ransom."

A NEW HOSPITAL FOR CHILDREN.

At a meeting of the New York State Hospital for the Care of Crippled and Deformed Children, held at the residence of Bishop Potter, the president, the committee on site reported that it had secured the lease of the residence of Dr. Angell, on the Hudson River, in Tarrytown, Westchester county, N. Y. The changes necessary to equip the building for hospital use will be made, and the hospital will be opened early in the autumn. The following were elected members of the consulting medical board: Drs. Francis Delafield, Robert F. Weir, W. Gilman Thompson, Joseph D. Bryant, Lewis A. Stimson, A. Alexander Smith, Reginald H. Sayre, of New York; Roswell Park, of Buffalo, and L. A. Weigel, of Rochester.

New York City.

Dr. Edward J. Ill has been appointed medical director of St. Michael's Hospital, to succeed Dr. Wm. Pierson, deceased.

An appropriation of $20,000 has been made to the State Board of Health for the purpose of fumigating the Chinese quarter and taking other precautions against the plague.

At a meeting of the corps of teachers of the New York School of Clinical Medicine, held at the Academy of Medicine, June 21, it was decided to wind up the affairs of the school and close it permanently. This action was taken in consequence of continuous interference of the lay board of trustees in its affairs.

ILLINOIS.

Dr. Margaret Shults has been appointed a member of the staff of St. John's Hospital, Springfield, to serve as pathologist and have charge of the children's department.

"Divine Healer" Schweinfurth has again come to the surface after a long submergence. It is now announced that his colony is scattered, that he has become a "Christian Scientist," and furthermore, that he has gone into business as a life-insurance solicitor. Evidently the divine healing business has not been found to be a permanent bonanza.

Chicago.

Dr. Nicholas Senn has gone to Southwestern Texas on a hunting trip.

Dr. Fenton B. Turck sails for Europe on the *Belgravia*, July 17.

Among those who sailed on the *Potsdam*, July 7, were Drs. E. T. Dickerman and W. H. Wilder.

Dr. James Nevins Hyde has gone to Europe to attend the International Dermatological Congress.

Dr. Boerne Bettman, the oculist, who went abroad for his health six years ago, has returned to Chicago, but is not yet able to resume practice.

A building at Calumet Heights, that will be immediately converted into a hospital with accommodation for about twenty-five patients, has been purchased by the South Chicago Hospital Association.

The number of blind children in Chicago, as found in the school census statistics, is 297; 160 boys and 137 girls. The needs of these children will be met by one school on each side of the city. These schools will be opened in September.

HEALTH DEPARTMENT.

Only one case of smallpox has been reported to the department during the past week. The patient, a colored man, 37 years of age, who has never been vaccinated, had been working with a gang of street pavers in Indianapolis. He was taken ill on July 2; three days later the eruption appeared, and on the next day he took the train for Chicago. He did not call a physician until July 9. The case was at once recognized as smallpox and the patient sent to the Isolation Hospital. The case is mild, but many have been exposed. The secretary of the State Board of Health of Indiana has been notified of the facts, that he may trace the source of the infection. Only eight deaths from sunstroke were reported for the week ending July 7, and the mortality from all causes was only slightly increased by the heat—thirty more than the preceding week and four more than the corresponding week last year. The total number of cases of contagious diseases reported was 96: scarlet fever, 43; diphtheria, 49; measles, 6. Fifty-two disinfections were made, and 13 funerals inspected. Of the 369 samples of milk and cream analyzed, 8.92 per cent. were found below grade.

OHIO.

Dr. Fannie C. Hutchins, for two years assistant physician at the Cleveland State Hospital for the Insane, has resigned.

Dr. Byron Stanton, professor of diseases of women and children in the Miami Medical College, has resigned, and his chair has been divided, Dr. E. W. Mitchell taking pediatrics, and Dr. R. B. Hall, gynecology. Dr. Mitchell's former chair materia medica and therapeutics, will be filled by Dr. Julius Eichberg.

By the will of the late Dr. James T. Whittaker, the Medical College of Ohio will become possessed of his library of nearly 1500 volumes. Among the especially valuable antique books in the collection are Celsus Medicinæ (1467), Opera Omnia Anatomica and Physiologica (1687), De Visonum Organis Generationia Inservientibus (1678), Elementa Physiologiae Corpus Humani (1777).

INDIANA.

Dr. B. C. Stevens, of Logansport, has gone to Europe for the summer.

At the graduating exercises of the Elizabeth Hospital training school for nurses, Lafayette, Dr. George Beasley, the president of the faculty, presented the diplomas.

MARYLAND.

Baltimore.

Dr. John G. Joy sailed for Europe, July 6.

Dr. W. B. Wolf has returned after a year's absence in Europe.

Dr. Jose L. Hirsh has gone to Wood's Holl, Mass., to spend some weeks in the laboratory there.

Two cases of smallpox were sent to the Quarantine Hospital, July 5 and 6, and thirteen colored men at Sparrow's Point, who had worked with the smallpox patients, were sent to the detention camp.

For the week ending June 30, there were 251 deaths, of which 127 were of children under 5 years of age. The death-rate was 24.12 per thousand, showing the usual proportion of about 1 white to 2 colored. From cholera infantum 71 died; from consumption, 23; from pneumonia, 13, and from diphtheria, 2.

BADGES FOR HEALTH OFFICERS.

The mayor has approved the ordinance requiring health officers of the city to wear badges as evidence of their official authority. They are to be of circular form with a red cross in the center, and with the title of the official at the head of the circle, and the words "B. C. Health Department" at the bottom. A fine of from $5 to $25 is provided for wearing the badge without authority.

CALIFORNIA.

Dr. F. M. Casal has been elected health officer of Santa Barbara, to succeed Dr. J. M. McNulty, deceased.

At the graduating exercises of the California Hospital Training School for Nurses, held June 27, at Los Angeles, Dr. F. T. Bicknell made an address and presented the diplomas.

SAN FRANCISCO MATERNITY.

The maternity department of the San Francisco Lying-in Hospital and Foundling Asylum was opened June 29. The attending physicians are Lucia M. Lane and Virginia W. Smiley; the consultants, Henry Gibbons, Jr., C. Van Hoffman, William Watt Kerr and D. W. Montgomery.

INTERNES FOR CITY AND COUNTY HOSPITAL.

The State Board of Health adopted a resolution, at the meeting of June 26, providing for the selection of thirteen internes for the City and County Hospital; five of these will be from the University of California Medical College and four from the College of Physicians and Surgeons.

MINNESOTA.

At the recent examination held by the State Medical Board, licenses were granted to fifty-four candidates.

The tenth annual commencement of the training school for nurses at St. Peter State Hospital was held June 29. A report of this year's work was made by Dr. Darling. Dr. Arthur Sweeney, St. Paul, delivered the address and Dr. H. A. Tomlinson presented the diplomas.

LOUISIANA.

New Orleans.

Dr. M. H. McGuire has been appointed resident physician to the New Orleans Sanitarium.

Dr. J. N. Thomas has been appointed to take charge of the Louisiana Quarantine Station at the mouth of Mississippi.

Dr. F. A. Larne is among the visitors to the Paris Exposition.

The medical department of Tulane University is adding instructors, made necessary by the four-year course. Dr. Ralph Hopkins will conduct quizzes on the lectures of Prof. S. E. Chaillé, professor of physiology, pathology and hygiene; Dr. J. Birney Guthrie will conduct quizzes on the lectures of Prof. L. F. Reynaud, professor of materia medica and therapeutics.

CONNECTICUT.

Dr. Ansel G. Cook, of Hartford, delivered the address at the commencement exercises of the Backus Hospital Training School for Nurses, at Norwich.

Yale University authorities are negotiating for the purchase of a site for the new medical school, adjacent to the New Haven Hospital.

The graduating exercises of the Yale Medical School were held June 26, and degrees were conferred on a class of twenty-six. Dr. J. M. DaCosta, Philadelphia, delivered the annual address on "Questions of the Day in Medicine."

NEW JERSEY.

Dr. George E. McLaughlin, of Jersey City, has gone to Europe.

The State Board of Medical Examiners met in Newark, July 5. Dr. William Perry Watson, New Brunswick, was elected president; Dr. C. L. B. Godfrey, Camden, secretary; Dr. Armin Uebelacker, Norristown, treasurer.

MONMOUTH MEMORIAL HOSPITAL.

The Monmouth Memorial Hospital at Long Branch, N. J., reports that during the past year 130 operations were performed. The surgical cases numbered 365; the number of medical cases was 176; the cash disbursed was $21,696.84, leaving a balance of $1,964.41 in hand; total number of patients admitted was 497; 17 cases were treated for appendicitis; of the 31 deaths, 2 died in from two to twenty-four hours after admission; number of patients cured was 320, improved 35, unimproved 5.

WEST VIRGINIA.

The regents of the state university have arranged for a medical department, and the following have been appointed members of the faculty: James W. Hartigan, professor of anatomy; A. E. Thayer, professor of histology, bacteriology and toxicology; A. R. Whitehill, professor of chemistry and toxicology; Otto Folin, professor of physiological chemistry; J. B. Johnston, professor of zoölogy; S. S. Wade professor of physiology; L. S. Brook, professor of materia medica and therapeutics.

CANADA.

Dr. G. S. Ryerson, Canadian Red Cross Commissioner in South Africa, sailed from Cape Town, July 4, for England, on his way back to Canada.

At the recent centennial celebration of the University of New Brunswick, at Frederickton, the degree of LL.D. was conferred on Drs. William Bayard and Boyle Travers of St. John.

Dr. Membry, late house surgeon for the Home for Incurables, Toronto, who went to Accra, West Africa, as Assistant British Commissioner, has been promoted to the position of Commissioner. He is about to start on an extended trip into the interior.

According to the prohibitory law of Manitoba, physicians will not be limited in the amount of liquor in prescriptions; druggists will not be charged any license; and veterinary surgeons and dentists will be allowed to procure and administer liquor in cases required by their respective professions. Provision is also made for hospitals, such as those at Brandon and Morden, which have no resident physicians.

THE HOSPITALS OF ONTARIO.

In the thirtieth annual report of the hospitals and charities of this province, which is for the hospital year of 1899, the detailed statements show to how great an extent charity is dispensed in Ontario. There are now fifty hospitals in operation in this province, and two more have been placed on the list for receiving government aid. The number of sick treated in these institutions during the past year amounted to 26,825, exclusive of the thousands known as outdoor patients. Nearly half a million dollars has been expended for the maintenance of these hospitals during the year. Of this amount the government contributed $110,000. In addition to these, there are about forty houses of refuge, thirty-one orphan asylums, four homes for incurables, three convalescent homes, eighteen county homes for the poor, and two Magadalen asylums, having an aggregate of 10,000 inmates, with a yearly expenditure for maintenance of $300,000, of which amount the Ontario government contributes $80,000.

BUREAU OF PUBLIC HEALTH.

Last week, Dr. G. G. Roddick, M. P., brought up this subject in the Dominion Parliament. He had been looking up statistics, and found that in doing so he had to go to two or three different departments of the public service, and he thought the subject sufficiently important to be concentrated under one bureau. He would consider it far better for the country if such a department were created and placed under a responsible head, and Dr. Montizambert would make an efficient deputy minister and sanitary adviser. In addition to this, he would have the direction of the marine quarantine act; as sanitary inspector of the Indian reserves, be director-general of the leper asylums, director-general of the Dominion Service of Vital Statistics, and have under his charge the sanitary portion of the census, the protection of waterways, sanitary police, and sanitary measures in unorganized territories, the protection of public health against the invasion of tuberculosis, the arrival of consumptive immigrants, and the importation of unhealthy articles of food and undesirable freight, such as rags. The question of sanitary police was particularly important, and these could co-operate with the various provincial authorities. He said that the Dominion should now have sanitary police in British Columbia to guard against the introduction of the bubonic plague, also the Dominion had need of a bacteriologic laboratory, for at present they had to depend on the United States, England and Japan. He said that he had recently attended a medical convention in the United States, where a medical man, who read a paper on leprosy, announced that he intended to visit Ottawa and make a study of the subject in the laboratory there, and he was compelled to inform this doctor that there was no such thing in Ottawa. He commended the organization of such a bureau to the consideration of the government, and, furthermore, made a suggestion that the government should have medical men in the great ports of Europe, who should carefully examine intending immigrants, and see that the ships were suitable, and properly equipped for the sanitary care of those on board.

Montreal.

Sir William C. Macdonald has offered to build a modern crematory for the city at his own expense.

Sir William Hingston has sailed for England, where he will be made an honorary fellow of the Royal College of Surgeons of England. This will be the first time this honor has been conferred on a Canadian physician.

SMALLPOX.

Scarcely had the last outbreak of smallpox been effectively suppressed, when the disease broke out again in a new quarter, and there are now six cases in the city, one of which is hopeless, the other patients are stated to be progressing favorably. One patient sent to the Royal Victoria Hospital, suffering from supposed obscure abdominal trouble, was subsequently diagnosed as smallpox, and as a result this hospital has been closed and no more patients are to be admitted until sufficient time has elapsed to warrant safe admission. Along with this new outbreak, comes a savage attack on the administration of the Montreal Civic Hospital by one of the victims of the previous outbreak, a man largely interested in mining matters, who was said to have brought the disease to Montreal from Rossland, B. C. This gentleman alleges gross negligence on the part of the health department of Montreal, which, he states, provided him with pavilion accommodation at first, of the vilest, most filthy and disgusting character; when he was afterward removed to the hospital proper, his surroundings were very little, if any, improved. He provided two nurses for his own personal care, and even then it was a very difficult matter to get the place in anything like habitable shape. These charges have excited much indignation among Montreal physicians against the board of health for the careless and ineffective administration of affairs.

PARIS LETTER.

THE BAZY-ALBARRAN DISCUSSION.

The recent meetings of the Society of Surgery have been in great part taken up with the discussion between Albarran and Bazy as to the merits or demerits of ureteral catheterization in renal tuberculosis. The war of words has been intense and, though Albarran seems to have silenced all the other men, such as Tuffier, Ricard and Bazy, it is more than likely that the subject will be taken up again at some future date. The cause of the discussion can be given in a few words: Dr. Albarran considers catheterization a relatively easy, safe and innocuous means of ascertaining the condition of both kidneys, and is in favor of removing a tuberculous kidney—when in initial stage of the disease or when the other kidney is found quite normal. Dr. Tuffier considers catheterization a difficult operation; and Dr. Bazy is opposed to the indiscriminate use of this mode of investigation; he prefers to trust to the usual methods of exploring the kidney, and considers the methylene blue test sufficient to indicate the condition of the kidney presumed to be still healthy. He, moreover, no longer advises only nephrectomy, but advocates surgical intervention when the kidney directly affects the patient by hemorrhage or by suppuration.

PROFESSIONAL SECRECY.

Professional secrecy is carried out to its extreme limits in France, and a recent occurrence shows how severe the law is in this respect. A midwife had, on her own responsibility, given damaging evidence against a woman whom she had confined. The court decided that such evidence should not be admitted, and the attorney-general had the case taken before the criminal chamber of the Court of Cassation. It was established that the court had decided rightly, and the judgment given shows that professional secrecy is no longer relative to the conditions laid down as to the responsibility of witnesses, but is absolute and without exception.

RAW MEAT IN THE TREATMENT OF CONSUMPTION.

Professor Richet has published recently an important article on the treatment of consumption by the use of raw meat. Three or four hundred dogs have been experimented on, and the results have been quite remarkable. The theory involved is quite new, as it seems to explain the action of this remedy by the antitoxic influence of meat-juice. Dr. Richet's communication has caused the publication of two articles on the same subject. Dr. Odolin Martin, of Lyons, has declared that by using dry meat-powder he has been able to observe, after two and one-half months, a most distinct change in patients suffering from consumption, and that signs of cicatrization were quite apparent after that lapse of time.

SMALLPOX IN LYONS.

Smallpox is still in evidence in Lyons, there having been 219 new cases and 47 deaths during May. This shows that the epidemic is relatively benign, compared with that in Marseilles, where 245 deaths took place during the month of December. There seems to be an antivaccination feeling in Lyons, as the health officers, on going into the poorer quarters of the city, were able to vaccinate only a small proportion of the whole population. In one large manufactory, also, only a few of the workmen would allow themselves to be vaccinated.

BACTERIOLOGY OF RHEUMATIC FEVER.

A work of some importance has just been published on this subject by Drs. Triboulet and Coyon. Three years ago Drs. Achalme and Triboulet made some researches on the bacteriology of rheumatism, and it was thought at the time that the microbes discovered were those of primary acute polyarthritis, or the usual form of rheumatic fever. More recent investigations, however, tend to show that these microbes play a secondary rôle in the creation of rheumatic fever, and that the real cause has not as yet been found. Still, it may be considered that they are the cause of the cardiac complications so often seen in this affection. This discovery might aid in determining, from the outset, what microbes exist in any given form of rheumatic fever, and thus might be a means of recognizing those forms of acute polyarthritis that are accompanied by valvular lesions. Achalme has already described an anaerobic bacterium, and certain staphylococci and streptococci have also been observed. A microbe called the "microbe of Coyon," has been found in the blood in certain cases. It is a diplococcus, and presents reactions which differentiate it clearly from staphylococci, streptococci or pneumococci. On inoculation it does not produce any special results, with one exception, where in a rabbit it caused valvular endocarditis, similar in nature and appearance to that seen in rheumatic fever. These facts are important, as they may allow the physician to determine the prognosis of the disease. It is thought that where staphylococci or streptococci exist, the complications will be very slight. On the contrary, when the microbes described by Coyon and Achalme are found, cardiac complications are much more apt to be encountered.

London Letter.

THE DUBLIN METHOD OF EXPELLING THE PLACENTA.

At the meeting of the Royal Academy of Medicine in Ireland, Dr. Henry Jellett read a paper on "The Dublin Method of Effecting Delivery of the Placenta." He remarked that in 1876 two well-known writers stated that the method of removing the placenta by external manipulation had been first introduced in Dublin, and that it was identical with the method which was introduced at a later date in Germany by Credé of Leipsic. Now all German and most British works on midwifery term this Credé's method." He describes the gradual evolution of the Dublin method from the time of Fielding Auld up to that of Sinclair and Johnston. Credé's method was brought forward prominently in 1860 at the meeting of the Association of Physicians and Naturalists at Königsberg, although it had been practiced in Dublin from time immemorial.

DEATHS FROM SUNSTROKE.

The four deaths which occurred at Aldershot from exposure to heat, among the soldiers engaged in maneuvers, have caused wide-spread indignation against the authorities. A field day was ordered and 30,000 men came on parade after breakfast, at a quarter past six. When the troops started there was exceptional heat, but about 10 o'clock great heat was felt, and "halt" was sounded at 10:30 and "cease fire" at 11:15. It was then directed that the men should march back as early as possible. A large number fell out and twenty-eight patients were received at the hospital, suffering severely from the exposure to the heat, of whom four died. The whole distance covered by the troops there was about fourteen miles. The head-dress worn was the small fatigue cap, which affords practically no protection. In the House of Commons, Mr. Wyndham stated that before this occurrence the adjutant-general was at work on a sun-shade to be attached to the fatigue cap. The commander-in-chief has now directed that helmets shall be worn, and that those men who, in consequence of the exigencies of the war do not possess them, shall not be allowed to undergo severe exertion at a distance from the barracks. Two years ago, when the fatigue cap was worn, sixty-one cases of sunstroke occurred at maneuvers. But such is the "hide-bound" conservatism of the war office that the deaths of these unfortunate men have been necessary to teach the military authorities to provide a rational head-dress for the soldiers. A few days after the fatal maneuvers the troops were again engaged in field operations, carried out in the early morning, and the men all wore helmets. But there was no sun; the weather was cold and damp!

WORLD'S TEMPERANCE CONGRESS.

The meeting of this organization has been held recently under the presidency of Mr. W. S. Caine, M. P. The president referred to the temperance problem in India, and stated that among the 70,000 British troops there, 23,610 were total abstainers.

Dr. T. D. Crothers, Hartford, Conn., read a paper on "The Scientific Study of Inebriety in America." He stated that the first medical authority who asserted that inebriety was a disease was Dr. Rush, of Philadelphia, who did so in 1809. There are now over fifty asylums in the United States and Canada where inebriates are treated medically: the opinions of authorities showing that about one-third of the cases are restored by the treatment.

Dr. James J. Ridge followed with an interesting account of the medical abstinence movement, stating that the discovery of distillation was made in the eleventh century, and that the manufacture of spirituous liquors began then. In Great Britain, it was not until the seventeenth century that the use of spirits spread like an epidemic. At the commencement of the nineteenth century, medical abstainers could be numbered by tens, to-day they are numbered by hundreds. The British Medical Temperance Association, founded in 1876 by a few medical men, now numbers 486 doctors and 515 students.

Mr. E. Wood read a paper on "Abstinence as a Factor in Promoting Health and Longevity." He said that the experience of all British insurance societies which had special sections for total abstainers proved conclusively that abstinence conduced to longevity. Thus the United Kingdom Temperance Institution expected 8048 claims in 34 years in the temperance section, while the actual claims were only 5724, or 70 per cent. In the general section, on the same actuarial basis, the expected claims were 10,369 and the actual claims 10,469, or 96.3 per cent. The most recent evidence was supplied by the Sun Assurance Society, which announced that total abstainers of at least two years' standing would be allowed an immediate reduction of 5 per cent. In the Foresters, a fraternal society, the average sickness was 12½ days per annum, per man—in the Sons of Temperance, only 7½.

NATIONAL SOCIETY FOR THE EMPLOYMENT OF EPILEPTICS.

This society is one of the most useful of the philanthropic societies of this country. At the annual meeting of the Governors, it was stated that among the epileptic "colonists" sent to the country residence at Chalfont, a marked improvement had been noted in the majority of instances. The principles followed are the removal of the epileptics to the country, their suitable employment, under direction, in a well-regulated life, avoidance of excitement, an abstinence from alcohol. The Chalfont colony has made rapid progress during the five years of its existence.

AUTOBIOGRAPHY OF SIR JOSEPH FAYRER.

The autobiography of Surgeon-General Sir Joseph Fayrer, K.C.S.I., LL.D., just published, is a record of a most interesting career. In 1853, he was appointed resident surgeon at Lucknow, where a most eventful period of his life was passed. The ideas entertained by rich natives of adequate professional fees might arouse envy, but Sir Joseph never accepted a larger fee than he thought just. When he restored to health one of the wives of an Indian king, in Durbar, the latter ordered 20,000 rupees to be sent him. He actually received 3000, and other gifts in kind. A little later the mutiny broke out, and he found himself shut up in Lucknow, to undergo the horrors of the siege.

CLINICAL LABORATORIES AT WESTMINSTER HOSPITAL.

The clinical laboratories which have been added to Westminster Hospital were opened in the presence of Lord Lister, the presidents of the Colleges of Physicians and of Surgeons and a distinguished audience. They are equipped with the latest apparatus, and the most recent microscopic, chemical and bacteriologic methods will there be applied in the diagnosis of disease.

OCCLUSION OF CENTRAL ARTERIES OF RETINA.

At the Ophthalmological Society, Mr, Jessop described a case of occlusion of both central arteries of the retina in a woman aged 35, who had been married nine years, and had no living children. She had had a miscarriage soon after marriage, and eight months ago she was delivered of a child at the ninth month, which lived only a few hours. On Oct. 24, 1899, while in apparently good health, on awaking, she found that she was blind in the right eye.. Signs of embolism of the central artery of the retina were found with the ophthalmoscope. On December 20, she suddenly lost vision in the left eye, and the signs of embolism were again found. Now both discs are atrophied and the retinal arteries are reduced to mere threads, and in paces there is a white thickened condition of the sheath—periarteritis. The vision of the right eye has improved to be 6/36, but with the left there is perception of light only. Mercury has been given. No source of the emboli could be suggested, but the condition is probably of syphilitic origin.

EPIDEMIC CEREBROSPINAL MENINGITIS.

At the Royal Academy of Medicine, in Ireland, Dr. Drury read a paper on this subject. He had met with 8 cases at the Cork Street Fever Hospital. The first patient, a man aged 20, was admitted on November 18, and after a prolonged illness recovered. Of the other 7 patients, 4 died. In only one case was there a rash—a typical feature of the great Dublin epidemic of 1866-67. This rash was not petechial, but pustular, with hemorrhage into the pustules, and came on late in the disease. In all cases the disease commenced suddenly, with rigidity of the neck or retraction of the head, and sometimes with opisthotonos. All the patients had deafness in some degree, pain in the head and limbs, and Kernig's sign. Dr. Falkner presented a table showing the number of deaths in Dublin from meningitis from 1895 till 1900. From 1895 till 1899, the average number of deaths from all forms of meningitis for the first nineteen weeks of each year was 102, but in 1900 it was 182, and the increase embraced ordinary tuberculous, cerebrospinal and secondary meningitis. Sir J. W. Moore said that in the present epidemic, he had found that the most successful measures were leeching and the repeated application of small blisters behind the ears. The agonizing headache was relieved by a combination of acetanilid, caffein. and sodium bicarbonate. Dr. O'Sullivan described post-mortem appearances in some of the cases. The fluid obtained by lumbar puncture was turbid, but colorless. The pus in the spinal region lay, in one case, outside the dura, the cord being apparently healthy. In the other cases, it lay in the meshes of, or underneath the pia, and the cord was softened. The diplococcus intracellularis was found in the turbid fluid, and in the pus, usually in pure culture. Professor McWeeny remarked that there was a disease of horses in which the essential lesion was a cerebrospinal meningitis. Intracellular cocci had been found in the pus, and it was quite possible that the disease might be identical with human cerebrospinal meningitis. Numerous cases had been observed in horses in Dublin—a fact of interest in connection with the present epidemic.

CERTIFICATES OF INSANITY.

The unsatisfactory condition of English law in the matter of certificates of insanity, is illustrated by a case just concluded. A coachman, in a state of great mental depression, consulted a medical man because his wife was pregnant, and he was alarmed at the responsibility of the future. His wife stated that he threatened to murder both her and her children. When seen at his house, the patient said "he heard voices which prevented him from sleeping." As his wife was still alarmed, the doctor communicated with the relieving officer, who removed the patient to the lunacy ward of the workhouse.

After three days he was discharged. He brought an action against the doctor, alleging that his detention was due to professional negligence. Expert evidence was given, showing the case to be of suicidal mania, that the defendant had acted most properly in the plaintiff's interest, and that rapid recovery was quite possible. A verdict for the plaintiff—the only possible one—was given, and the defendant was mulcted in costs. This means that of the expenses incurred in defending the suit, probably at least $500, a portion cut down by the taxing-master to the lowest figure will be due from the plaintiff. Considering the plaintiff's position, it is probable that the doctor will never be able to recover a penny. This is the state of English law: A medical man in the discharge of his duty in securing the detention of a patient who is a danger to himself, to his family, and perhaps even to the public, is exposed to the inconvenience, anxiety, and cost of legal proceedings. It is not to be wondered at that, as a result, many doctors will under no circumstances sign a lunacy certificate.

BORIC ACID AND FORMALIN AS MILK PRESERVATIVES.

A number of prosecutions of milkmen for selling milk to which boric acid or formalin had been added as a preservative, has resulted in fines being imposed of from ten to fifty dollars. There was some conflict of medical evidence whether the quantity of boric acid present was injurious. In several cases the cream contained .5 per cent. of boric acid. Professor Boyce stated that this quantity would be injurious if taken continuously. He based his opinion on experiments made by him on kittens, in which the boric acid retarded digestion. Dr. Rydial, a public analyst, stated that he had made a special study of the subject. He agreed with those who said that a certain proportion of boric acid was poisonous, but this depended on the quantity taken. To get a medicinal dose of boric acid 700 to 800 cups of tea would have to be taken. Borax and honey were recommended for infants by nine out of ten monthly nurses. He had never heard of less than fifteen grains a day injuring an adult, or five grains a child.

WOUNDS IN THE BOER WAR.

One of the most remarkable facts established by the South African War is the great humanity of the modern bullet, and the possibility of rapid and complete recovery from wounds of almost any organ of the body. The brain, lungs, liver and abdomen have been traversed by bullets, with comparatively trivial results. The only vital organ for the Mauser or Lee-Metford bullet seems to be the heart. Many of the ideas previously held as to treatment have been quite exploded. The percentage of recoveries among the wounded treated at the hospitals has sometimes been as high as 96. Mr Treves stated that in his experience 60 per cent. of those shot in the abdomen recovered without operation, while, on the other hand, the result of operations in the field was bad. He considered that laparotomy was indicated only when the patient was seen within seven hours of the injury, and only when the transport was short and easy, when the wound was anteroposterior above the umbilicus, and the bullet had escaped, when there was excessive hemorrhage, and in some wounds below the umbilicus with escape of the bullet, especially if hemorrhage had occurred. He attributed the high rate of recovery without operation to the fact that most of the men, when shot, were fasting, that peristalsis was inhibited for some time by the shock, and that the Mauser bullet makes a very small "slit-like" hole in the intestine. In wounds of the knee-joint, amputation was scarcely ever performed, and in most cases recovery was rapid and the mobility of the joint was little, if at all, impaired. This is in strong contrast with Sir Thomas Longmore's report that in the Crimea "Not one wound of the knee-joint recovered without operation," and the fact that in the Civil War out of 3355 recorded cases, 2431 were treated by amputation at the knee-joint or through the thigh, with a mortality of 55 per cent.

GASTROENTEROSTOMY FOLLOWED BY PYLORECTOMY.

At the Clinical Society Mr. Arthur E. Barber described a successful case of this kind in a woman, aged 55, who had symptoms of partial intestinal obstruction, and a tumor to the left of the left rectus muscle under the border of the ribs. On abdominal section the tumor was found to be a cancer of the pylorus. Retrocolic gastroenterostomy was performed, and five weeks later the pylorus was removed and the resulting openings in the stomach and duodenum closed. The patient recovered rapidly, increased in weight, went about as usual, and ate ordinary food. She died from recurrence one year after the operation. Murphy's button was used, and was passed on the twelfth day. The operation was much facilitated by taking it in two stages.

MIDWIVES' BILL.

The discussion and excitement produced by the "Midwives' Bill" is subsiding. By this measure it is proposed that the government shall regulate the practice of midwives. They will be registered, and in future an examination will have to be passed by every woman who desires to be placed on the roll of those who present themselves to attend normal labor for the purposes of gain. The violent and unreasonable attack on the measure made by those who are supposed to represent the interests of the general practitioner has been quite ineffective, and has only served to make the public regard the profession, or at least that part of it, as actuated by the most sordid motives. The cry was raised that a new and ill-instructed order of medical practitioners was being created, into whose hands the destinies of the parturient woman were to be confided, much to her disadvantage. But the fact is that already—from economical or other motives—considerably more than half the labors in the country are attended by midwives. The question, therefore, is—and the agitators decline to face it—should the public be left at the mercy of the ignorance and incompetence of many of these women, or should a better and properly trained class be created? The men who profess so much solicitude for the parturient woman, and who are horrified at the idea that she should be attended by a properly trained midwife, were never troubled by the fact that she was being attended by an untrained one. The bill has passed its second reading in the House of Commons by a large majority, and the most the opponents now hope for is to be able to modify it.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC.

This institution continues to make steady progress, in spite of the ill-feeling and jealousy which its inauguration has aroused, in a small circle, among some of the older institutions. While the smaller metropolises of every country in the world have for many years made ample provision for post-graduate instruction, nothing worthy of the name existed in London before the establishment of the Polyclinic. ,Some distinguished surgeons yet regard it as a most unnecessary innovation, and the greatest and most authoritative of medical journals, the views of which are rightly received with respect all over the world, doubted its utility and said that it would "abstract much energy from existing institutions." Truly we are a conservative people! A dinner in order to raise funds, of which the Polyclinic is still in great need, has just been given at the Trocadero Restaurant, under the presidency of Lord Strathcona and Mount Royal, formerly High Commissioner for Canada. He was supported by Sir William Broadbent, Mr. Jonathan Hutchinson, and many other well-known men. About £600 was subscribed.

THE HILL STATIONS OF INDIA AS HEALTH RESORTS.

At the meeting of the British Balneological and Climatological Society, Sir Joseph Fayrer delivered an address on this subject. He considered these stations not merely in reference to the treatment of disease but also as resorts in which Europeans might preserve health and avoid the physical deterioration of protracted residence on the plains, and where it seems even possible that they might thrive and propagate. History shows that colonization of the plains is impracticable. Of the Portuguese, who preceded the British, no descendants without an admixture of native blood exist. Every variety of climate is met in India. Malaria is wide-spread on the plains, and here Europeans can not exist for any continuous length of time, but there are many hill stations where they can live, and many other localities which have never been explored. There are good reasons to suppose that in the vast mountain ranges and tablelands of India the physical and climatic conditions necessary for the preservation of health, and perhaps even for colonization by Europeans, exist to a much greater extent than has been heretofore supposed.

RAISING THE STANDARD OF PRELIMINARY EDUCATION.

A further attempt to raise the standard of medical education is now being made by the General Medical Council. At the last meeting Sir John Batty Fulse presented a report by the Education Committee on the question of raising the standard of preliminary examination in general education. Detailed suggestions were made as the result of reports received from experts throughout the United Kingdom. It was also proposed that an age limit should be fixed, below which an applicant could not be registered as a medical or dental student. The committee proposed that this limit should be fifteen. At some future time, when the standard of preliminary education had been raised, it might be advisable to raise the limit to seventeen. This would have the effect of inducing those who intend to enter on the study of medicine, to spend a longer time over ordinary school subjects, thereby better fitting them for the more stringent examinations it was proposed to require.

Correspondence.

Rambling Notes of a Roving Doctor.

VIENNA, AUSTRIA, May, 1900.

NAPLES—PELLIGRINI HOSPITAL.

To the Editor:—After my arrival in Europe from the far East, I spent several weeks at Naples, and while there, made frequent visits to some of the principal hospitals. The Pelligrini has one hundred and fifty beds, and its service is entirely devoted to the treatment of accidents and emergency cases. While the Englishman usually uses his fists to wreak his vengeance on his enemy, the Italian is prone to use a knife or a revolver, whichever happens to be at hand, and he usually has one of these weapons on his person. These cases are all brought to the Pelligrini for treatment, and I believe that this is the richest field in the world in which to study, in civil practice, gunshot and stab wounds. I made my visits here early in the morning, and never failed to find from two to six fresh cases for examination and treatment. Fresh knife wounds are dressed with moist gauze, wrung out of a 1 to 1000 carbolic acid solution. Wounds about the head and face, if much infected, are usually cleansed with this solution, and then allowed to heal by granulation without being stitched. In the treatment of penetrating wounds of the abdomen, whether made by a knife or pistol ball, one universal rule is followed, that is, to open the peritoneal cavity at once and carefully examine all its contents. It makes no difference whether the patient has any symptoms or not, this rule is most strenuously enforced. If the intestines are uninjured, and the other abdominal organs intact, the operation has been simply of an exploratory character and the patient will have suffered no harm. On the other hand, if it is decided to wait for symptoms of intestinal injury to develop, the delay will have been too great and the case will terminate fatally in spite of interference. In closing wounds of the intestines, two rows of fine silk sutures are used, the first including both the mucous and serous membranes, the second, the serosa alone. I noticed a set of Murphy buttons among the instruments and asked the surgeon, Dr. Jacobelli, if they used this appliance often in their intestinal work. He said that they did not, and that in the few cases in which they had used it, they had experienced trouble and that there had been delay in its passing from the bowels. He thought, however, that the Murphy button was a wonderfully ingenious appliance and had a place in intestinal surgery, but that that place was limited mostly to operations done by men who had little experience in this kind of work.

In cases where an intestine has been wounded, and a portion of its contents has leaked out into the peritoneal cavity, unless this leakage has run over a very large surface, the parts are never irrigated, but are simply sponged out with dry gauze. They claim that the attempt to cleanse a circumscribed contaminated surface by flooding the parts with water, must necessarily infect the whole serous surface of the abdominal cavity.

In operating for hernia, they follow to the letter Bassini's technique, and though they appeared to take great pains in their antisepsis, nearly all the wounds suppurated before they healed.

I saw some very good orthopedic surgery done in Naples. In cases where it is necessary to fracture a long bone to remedy a deformity, they divide the bone for about one-third of its thickness with a chisel, and then break it with the hand, ignoring all the powerful appliances made for that purpose.

VIENNA AS A MEDICAL CENTER.

For the fifth time during the last quarter of a century, I find myself in the Austrian capital, and while I prefer this city as a place of residence to any other in Europe, the chief attraction of Vienna for me has always been her advantages as a medical center. When I first came here, this was the only city in the world where post-graduate instruction was systematically given. At that time I was more ambitious than I am now, and knew less exactly what I ought to study; hence I tackled everything, including the eye, nose, throat, skin, obstetrics, gynecology, general surgery, internal medicine, and, in fact, whenever I saw a private course on any subject whatever bulletined inside of the walls of the *Allgemeines Krankenhaus*, I took that course. During my last two visits here, I have devoted myself mainly to that most important but most neglected branch of our profession, internal medicine, together with such laboratory and dead-house work as would aid me in better comprehending this subject.

I propose in this letter to advise my readers who should come here and who should not. A young physician of moderate means, with little or no knowledge of the German language, who has been graduated four or five years, and can not be absent from his field of labor more than three or four months, unless he is a fraud and is going abroad just for the name of the thing, would better stay at home and do his work at one of our own schools, where he can get much more that will benefit a general practitioner and in a shorter time, than he can anywhere in Europe. On the contrary, if he wishes to study a specialty, like the eye, nose, throat, skin or venereal disease, I know of no place where one can be better taught than in Vienna; but to receive the full benefit of such teaching, he must know German. To do this alone will take him three or four months, during which time he will have learned only a little of his subject, and that by the sense of sight.

On my way from Venice to Vienna, I met a bright young Chicago doctor who was coming to Vienna for surgery. He knew no German. He told me further that he had been an assistant of Professor Senn at the Presbyterian Hospital for one year. I told him he would find himself like the man from Newcastle who had left that city in search of coal. I saw him many times after and he always wore such a downcast, dejected, disappointed look, that I pitied him from the bottom of my heart. Vienna is, and has been for a quarter of a century, one of the most disappointing places in which to see surgery that I have visited. Billroth, although a learned and scientific man in the branch he taught, was a wretched instructor; Gussenbauer, his successor, is very little better. It is the ambition of every student who studies at one of the surgical clinics here to become an assistant. If he gets this position, he prints the fact in large letters on his cards and puts it on his sign when he locates for practice. The result of all this is that Gussenbauer has about twenty-five assistants, and that when a patient is put on the table in the amphitheater for operation, these fellows, dressed in white gowns, hover around the table like vultures around a carcass, and no one else can see anything that is being done. On two successive days Gussenbauer resected the pylorus for cancer. He had twenty assistants around him, and the seventy-five men who sat on the benches of the amphitheater might just as well have been seated in a café across the street, so far as getting any benefit from the operation was concerned. Albert, on the contrary, is a fine teacher, but does not himself operate, leaving all that kind of work to his assistant, Dr. Ewald. The lecture room in which these two men teach and operate, is most crowded, stuffy and uncomfortable, and I avoided it as much as possible. I believe that our surgeons in the United States are better guides than are foreigners, because we are more careful of human life.

For one who is looking after gynecology, the only advantage that Vienna offers over the United States is the number of patients that he can examine with a view of making a correct diagnosis. If, however, he wishes to see gynecological operations, he can see more of such work in the United States, and see it equally well or better done. The only way one can become a welcome visitor to either of the two gynecologic operating-rooms in Vienna, is to take the private courses given by the first assistants to these departments, which are the most expensive of any given in the *Allgemeines Krankenhaus*.

I believe that the only advantage for the study of surgery here is for the young man who wishes to learn this branch by operating on the cadaver. Several of the assistants at the surgical clinics give courses where one can do all important operations on the dead body, under the eye of a competent teacher. In connection with these courses, surgical diagnosis is taught, using the large outdoor material for that purpose. In the matter of obstetrics, I do not believe there is any place in the world where one can find so much material as in Vienna and where it is so thoroughly utilized for teaching purposes. To be benefited by what can be obtained in this line, at least six months' stay is essential, and a considerable sum of money must be paid to assistants. If one attends one of the lying-in clinics for six months, he can see a number of normal labors and be present and assist at as many obstetrical operations as he would be likely to encounter in a lifetime of practice.

In my opinion, however, the teaching of internal medicine in Vienna gives a student better advantages than are to be obtained at any other place. I am glad to see that this opinion is being held and acted upon by a large number of the young American physicians. Twenty years ago I found myself the only English-speaking student among a class of ten men studying this branch of medicine. To-day, over ten out of about eighty American post-graduate students who are in Vienna are studying internal medicine. Two of the best men who teach this subject have classes composed exclusively of Americans, and to get into one of these classes, one has often to apply weeks ahead. The teachers in Vienna are no better than our best men at home, but the material in the hospitals here can be better utilized for teaching purposes than at any place I have ever been on the other side of the Atlantic.

The prime defect in all medical teaching in the United States is the didactic lectures, and as long as this system is kept up, illy-qualified men will be sent out to practice medicine. A strange feature of this subject is that the Anglo-Saxon still persists in this most faulty mode of giving instruction in this important branch of our profession. Some years ago, I gave my card to Dr. Reese, of Guy's Hospital, London, and asked the privilege of attending his lectures for a few weeks. He asked me where I had spent my time while abroad and I told him I had just left Berlin, where I had attended Frerich's clinic at the Charité. He replied, "You would better have stayed there, for as compared with what you get there, you will find anything you will get in London very thin." And thin I found it, for he read his lectures from a manuscript and his class amused themselves by throwing paper balls at each other's heads.

Though the private courses given in Vienna are given by assistants, many of these men are as good teachers as the professors themselves. Nothnagel, Neusser nor Schrotter never appears before a class to deliver a lecture, without a patient to illustrate the subject.

EXPENSE IN VIENNA.

As the matter of expense is a subject of interest to the majority of students who come to Vienna to study medicine, I will close this letter by giving a few items of information on that point. The best way to live is to rent a small furnished apartment and take meals at a café or restaurant. A suitable room for two persons will cost about twelve dollars per month and board one dollar per day. Private courses generally cost forty cents per hour, though some are much more expensive. The laboratory and the dead-house course in internal medicine with many post-mortems, and bedside instruction, all told, will cost $1.25 per day.

W. S. Caldwell, M.D.

Typhoid Fever in the Second Pennsylvania Infantry.

Ann Arbor, Mich., July 2, 1900.

To the Editor:—In your issue of June 30, Dr. Francis R. Packard wishes to know from what source I obtained authority for the statement: "The claim is made by an assistant-surgeon of one of the Pennsylvania regiments that there was not a case of typhoid fever in his command, but the records of the Philadelphia hospitals show that certain cases sent from this regiment proved to be typhoid fever."

My authority for the statement will be found on page 85, Volume xiv, "Transactions of the Association of American Physicians." In the discussion of a paper read by me, Dr. S. Solis-Cohen made the following statement: "It is a matter of record that Col. J. Biddle Porter's regiment, the Second Pennsylvania, had no typhoid fever, and but two cases of illness from any cause." It is true that Dr Packard states in his article concerning the health of this regiment: "Before proceeding further, I would premise by stating that throughout the regiment's stay in camp there was but one death, that of a sergeant, who did not come to the hospital at Penn's Grove until two days before his death, and who was then delirious and in a practically moribund condition with typhoid fever. He had been absent in Philadelphia for some time previous to his illness. There was no other case of typhoid fever in the regiment, nor was there a single other case of really serious illness of any kind."

The statement in my paper should be changed to read as follows: "The claim is made by an assistant-surgeon of one of the Pennsylvania regiments that there was but one case of typhoid fever in his command, but the records show that certain cases sent from this regiment proved to be typhoid fever." I know very little about the medical history of the Second Pennsylvania. In the division of our work among the different members of the board, this regiment fell to Major Shakespeare, and I have no doubt that his part of the report will contain a full and accurate description of the diseases of this regiment. I have a list of deaths from all the regiments, obtained from the office of the Adjutant-General in Washington. This official record credits the Second Pennsylvania Infantry with two deaths from typhoid fever, as follows: "William C. Hagen, Corporal of Company D, died in Philadelphia, November 4, of typhoid fever; David McGlensey, First Sergeant of Company F, died August 15, 1898, at the camp at Penn's Grove, of typhoid fever." This last is undoubtedly the case referred to by Dr. Packard in his paper on the health of the regiment. I have not a complete list of the sick from this regiment, but on a slip of paper sent me some months ago by Major Shakespeare, I find the following record: "Rudolph King, private of Company A, of the Second Pennsylvania, admitted to Jefferson Medical College Hospital, Philadelphia, from quarters, Sept. 19, 1898; discharged Oct. 22, 1898; Austin Halman, private of Company A, Second Pennsylvania, admitted to Samaritan Hospital, Philadelphia, Sept. 17, 1898, from quarters; discharged Oct. 22, 1898." I do not know whether this includes all the cases of typhoid fever reported from this regiment or not.

I am very glad that Dr. Packard has called my attention to the misstatement made in my article, and I will be glad to correct the same. The members of our board have been very anxious to have every statement absolutely correct, and I will thank anyone who will point out errors of fact or statement in any of the papers which I have read on the subject.

Dr. Packard states in his article in The Journal: "Not a single case of illness of any kind whatsoever was sent from our regiment to a Philadelphia hospital during our entire camp life." It will be seen from the names quoted above why I made the statement I did about the sending of patients from the regiment to the Philadelphia hospitals. When an official record states that a patient was admitted "from quarters," it is understood that the patient came from the regiment or company camp. It is easy, however, to explain how it is that Dr. Packard makes his statement. The regiment, as he states, returned to Philadelphia September 15, after which he had no control or even knowledge of the sick, and the above-mentioned cases were admitted to the hospital after that date.

Victor C. Vaughan.

Increase in Venereal Disease in Paris.

PARIS, FRANCE, May 10, 1900.

To the Editor:—An evil almost inseparable from all World's Expositions is the great increase in the number of venereal diseases. Not only are the native contributors to immorality largely increased by the presence of a greater pleasure-seeking population, but a great influx of prostitutes from all parts of the world adds to the enormous number of clandestine debauchees. The statistics of l'Hôpital Ricord show an increase out of all proportion in the number of soft chancres during exposition years. This is explained by Prof. Fournier as due to the large increase in clandestine prostitution, and to the importation of a more uncleanly class during this time. This fact about the soft chancre is so well known that Mauriac, at l'Hôpital Ricord, when requested to send over cases with the Ducret-bacillus, some months ago, replied, *"Eh, bien! Il faut attendre pour l'ouverture de l'Exposition."*

As syphilis is recognized to be, with alcoholism and tuberculosis. one of the great scourges of France, we consider as very apropos, the lecture of Prof. Alfred Fournier, May 4, in the Amphitheatre of l'Hôpital St.-Louis, on "Sterilization of Syphilis." The audience, composed principally of foreign physicians, showed an interest in the humanitarian aspects of the subject which would put to shame the prudish position taken by many American and English physicians who would consign the whole question to oblivion.

Professor Fournier considered the word "sterilization" to include all means used to prevent the transmission of the disease, by measures applied directly to the individual infected; so that this one case, at least, should not produce another. As illustrating syphilis of the sterile type might be mentioned for example an honest, intelligent, and careful man who might unfortunately contract syphilis, but who in his regard for the welfare of others would follow carefully the hygiene and treatment ordered him and would wait until cured before contemplating matrimony. Such a case would remain sterile as to further transmission. On the other hand, as a type of syphilis fecund in results take a woman, careless of her person, ignorant, lazy, who only follows treatment the shortest time possible; let her develop contagious accidents and she may transmit the disease to three or four persons, not to mention the case of a prostitute, who, in a public house, having three or four sexual *"rapports par jour,"* may sow the disease broadcast. The number of men infected by these women may be learned by reading army reports where the military laws compel the soldiers to denounce the woman by whom they were infected. Cases are reported of ten, twenty and thirty men who have been infected with syphilis by the same woman. In a report recently read before the Academy of Medicine of Paris by one of the examining physicians of the service of firemen the case of one woman was reported, who infected thirty-five firemen. In another case, a girl of 17 showed on examination enormous mucous patches of the vulva which had existed for six months, during which entire time, not excepting her menstrual periods, she had had an average of three connections a day, with the patrons of the low wine-room where she was waitress. Allowing that four hundred and fifty men had been exposed to contagion and that only one in three had been infected, we have the enormous total of one hundred and fifty cases of syphilis contracted from one woman. Such appalling facts bring us to consider the conditions which influence the fecundity or sterility of syphilis.

1. The intelligence of the subject. The careless, thoughtless, ignorant prostitute has an amazing fecundity of transmission as compared with an honest mother infected by her husband, in which latter case there is almost no further transmission.

2. Too short or insufficient treatment, which may be due to no lack of conscientiousness on the part of the patient, but to insufficient emphasis by the physician on the necessity of prolonged treatment.

3. Quality of the syphilis, benign or malignant. Often the benign cases are especially dangerous by reason of the insignificance of the primary lesion, and the trifling inconvenience from the mucous patches. Heavy smokers are also liable to a recurrence of mucous patches ten to twenty times.

4. Inability to hospitalize the cases, which, if practicable, would render the disease infecund by sequestration.

5. Social conditions, poverty and crowding in tenements, which by favoring promiscuity in the use of household and toilet articles and eating utensils, favor fecundity of infections.

6. Professional conditions. Glassblowers, whose trade compels the passing of the same tube from mouth to mouth, suffer regular epidemics of syphilis when a man with mucous patches is admitted to their number. In France, women whose profession consists in forming and developing the nipples of young mothers have spread small epidemics of syphilis by inoculation of fissures in the nipples from mucous patches in the mouth. Vaccinators in rural districts, when human lymph was used, infected hundreds of cases. In Russia, professional cuppers have infected as many as two hundred cases by means of infected cupping instruments.

Fournier considered five syphilitic lesions as principal agents of transmission: 1, chancre: 2, erosion or mucous patches (secondary); 3, ulcerations (tertiary); 4, blood in secondary state, and 5, vaccin.

Of the first two, the chancre played a small part, while the mucous patches played an enormous rôle; out of twenty cases caused by the two, the mucous patch would cause eighteen, the chancre two. This is easily explained by the transitory character of the chancre, which disappears after two to three weeks, never to be reproduced, while the mucous patch may recur twenty, thirty or forty times; multiple localization of mucous patches on the lips, mouth, tongue, vagina, vulva, glans penis, and skin; their long period of recurrence after many years, being especially dangerous during the three first years; and the fact that the lesions are regarded as so trivial emphasize the importance of this manifestation. Ninety-nine per cent. of married men who infect their wives do so by mucous patches. The great point in the prophylaxis of syphilis is sterilization of the mucous patch, which must be done again and again as often as it recurs.

What are the means of sterilizing syphilis?

1. Sterilize by thorough, long-continued and completely-carried-out treatment.

2. Instruct patient regarding danger incurred by others in all forms of personal contact, even an innocent kiss on the cheek. Give printed instructions to avoid allowing anyone to use the knife or fork, glass, comb or brush used by patient. Advocate giving a small printed brochure with some elementary facts in regard to the disease, not painted so as to alarm, but so as to impress on the patient the gravity of the disease and the means to be adopted to prevent communication. Fournier favors hospital conferences or lectures especially gotten up for syphilitics, not burdened with pathologic descriptions, but hygienic advice how to get well, and how to prevent others contracting the disease.

3. Relieve excessive crowding of clinics. At St. Louis, out of two or three hundred cases every morning who pass before the consultant, forty or fifty syphilitics would take up too much time to properly instruct. Increase the number of venereal clinics. Make obligatory on all medical students to serve a sufficient length of time in a venereal clinic to become competent in recognizing syphilis.

4. Hospitalization with sequestration of the patient and his disease would render the greatest service. This would be necessarily impossible, inasmuch as the period of disease extends over two or three years and the treatment would be immensely expensive, and as, even if hospital facilities were afforded, patients would not enter for so apparently simple a thing as a mucous patch of the lip.

5. Surveillance and compulsory seclusion of prostitutes known to have syphilis in any form. This method of police surveillance and seclusion has been attacked more violently than ever by the puritanical British Purity League, which would abolish all vigorous measures against prostitution. This league, which, gloating over its victory in suppressing the Contagious Disease Act of England, in 1886, is stretching out its baneful influence toward the continent, should be as vigorously fought by all medical men as the antiquated idea that all epidemics were visitations of Providence. All the cant of

the league about the medical visits of inspection being outrages to their sisters, the prostitutes, is simply ridiculous. The law, while in no way approving or sanctioning prostitution, must exert its rigors of inspection and policing on the women, as they only put themselves on the market. While there are only 5000 prostitutes in Paris under police surveillance, the great danger comes from the infinitely greater number of clandestine prostitutes. To demand the complete abolition of all police control over these women because all cases of syphilis are not detected would be as reasonable as to abolish all the gendarmes because all the thieves are not caught. While heartily in favor of all moral reforms, such as early marriage, asylums for reclaimed fallen women, elevated moral life, etc., medical men must remember that their obligation to society is not to question the morals of the case, but to cure and prevent disease.

Fournier advocated as reforms in the consultations for the poor:

1. Relieve the strain on present clinics by a large increase in venereal dispensaries, which shall be open every day and shall have night séances.
2. Render them easy of access; prevent the long waits as at present; encourage rather than repel their applications for relief.
3. Make the consultations approach as nearly as possible the private city consultations, so that the patient will not be compelled to relate his history before his fellow patients.
4. Make them free, instead of paying as at present, for the loss of time as deducted from the wages of women is fifteen to forty cents, for men, eighty cents to a dollar a day. They should not be compelled to lose this money in order to be treated.
5. Consulting physicians should pass competitive examinations, and should be expert in venereal diseases.

He concludes by saying that the *dernier ressort* was the prophylaxis by treatment to the extermination of the disease.

A. D. Mewborn, M.D.

Alcohol as a Food.

Clarendon, Texas, June 13, 1900.

To the Editor:—I am surprised to see in *The Dallas News*, an editorial which quotes The Journal, and other medical journals, as authority for the statement "that alcohol can not by any scientific evidence be called a food." I supposed that all scientific medical men of this day had long since accepted as a fact established, and no longer *sub judice*, that alcohol up to a certain amount was consumed and utilized as food. I am therefore exceedingly surprised to see a reputable medical journal discuss the subject at all, and, of course, much more so to find it lending its influence to the propagation of false teaching. I have at hand the latest and most authoritative teachings on the subject which agree fully with my observation and experience that, in the language of one of these authorities—Thompson—"In many cases of malnutrition, and malassimilation of food, alcohol is itself a food, and its consumption under proper direction, results in an increase of bodyweight and strength and improvement of functional activity," and "there are a number of diseases in which the use of alcohol is a positive service, and in which it becomes a necessity in order to save or prolong life."

H. I. Winn, M.D.

Deaths and Obituaries.

Alexander Johnston Chalmers Skene, M.D., of Brooklyn, N. Y., who died from a cardiac ailment on July 6, at his summer home, at Highmont, in the Catskills, was born in the parish of Fyvie, Aberdeenshire, Scotland, June 17, 1837. His family, one of great antiquity, includes warriors, statesmen and professional men, who were closely identified with the history of Scotland. He came to America at the age of 19 years, with a strong liking for zoölogy and the study of medicine. After a course at the University of Michigan, he proceeded to the Long Island College Hospital, from which he was graduated in 1863. The Civil War was then at its height, and he served as an acting assistant-surgeon, at David's Island, N. Y., and Port Royal, Charleston, S. C. After the war he identified himself with his alma mater as an adjunct professor, and soon became known as a diagnostician of singular acumen. As a gynecologist he had an international reputation, to which a masterwork published in 1883 liberally contributed. He was a purist in style, a careful collator of facts, and an original classifier, besides being a lover of art and an amateur sculptor. His name is on the rolls of many medical and scientific societies.

J. H. Burnett, M.D., Mariposa, Cal., died June 22, from epithelioma of the face. He was graduated from the Louisville National Medical College in 1891, and had since practiced in Mariposa.

George G. Saxe, M.D., formerly of Watertown, S. D., and a graduate of the College of Physicians and Surgeons, New York City, died at his old home, Madison, N. J., June 25, aged 55 years.

Bennett Bussey, M.D., Biggs, Cal., died June 25, aged 93 years. He was graduated from the department of medicine in the University of Maryland, in the class of 1828.

J. T. M. Cardeza, M.D., of the class of 1844, medical department of the University of Pennsylvania, died at his home in Claymont, Del., June 28, aged 79 years.

A. J. Battle, M.D., Wadesboro, N. C., died June 19. He was a graduate of the College of Physicians and Surgeons, Baltimore, Md., in the class of 1881.

Chas. A. Mackin, M.D., Milford, Mass., died June 29, aged 60 years. He was a member of the class of 1866, Harvard University Medical School

John Ashhurst, Jr., M.D. We regret to announce the death of Dr. Ashhurst, at Philadelphia, on July 7. A notice of his life and works will appear in the next issue of The Journal.

Edward S. Reynolds, M.D., Jefferson Medical College, Philadelphia, died at his home in Bellevue, Pa., July 1, aged 46 years.

Louis E. Bonne, M.D., Northwestern University Medical School, Chicago, 1893, died at his home in Chicago, June 25, aged 35 years.

Louis Arcularius, M.D., University of Giessen, Germany, 1867, died in New York City, July 1.

DEATHS ABROAD.

We note the deaths of:

E. Dadet de Gassicourt, professor of pediatrics at Paris, founder of the *Revue Mensuelle des Maladies de l' Enfance*, and secretary of the Académie de Médecine.

Dr. Kuehne, director of the Institute of Physiology at Heidelberg.

Books and Pamphlets.

Acknowledgement of all books received will be made in this column, and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review as dictated by their merits, or in the interests of our readers.

BOOKS.

Diseases of the Chest, Throat and Nasal Cavities; Including Physical Diagnosis and Diseases of the Lungs, Mediastinum, Heart and Aorta, Laryngology and Diseases of the Larynx, Pharynx, and Nose and Special Diseases of the Thyroid Gland and Esophagus. By E. Fletcher Ingals, A.M., M.D., Professor of Diseases of the Chest, Throat and Nose, Rush Medical College. Fourth Edition. With Two Hundred and Fifty-five Illustrations. Cloth. Pp. 765. Price, $4.50. New York: William Wood & Co. 1900.

Annual and Analytical Cyclopedia of Practical Medicine. By Charles E. de M. Sajous, M.D., and One Hundred Associate Editors, Assisted by Corresponding Editors, Collaborators and Correspondents. Illustrated with Chromo-Lithographs, Engravings and Maps. Volume v. Cloth. Pp. 662. Price, $5. Philadelphia, New York and Chicago: F. A. Davis Co. 1900.

Tuberculosis: Its Nature, Prevention and Treatment. With Special Reference to Open-Air Treatment of Phthisis.

By Alfred Hillier, B.A., M.D., C.M., Fellow of Royal Medico-Chirurgical Society, London. With Thirty-one Illustrations and Three Colored Plates. Cloth. Pp. 245. Price, $1.25. London, Paris, New York and Melbourne: Cassell & Co. 1900.

A Manual of Obstetrical Technique as Applied to Private Practice. With a Chapter on Abortion, Premature Labor, and Curettage. By Joseph Brown Cooke, M.D., Late Attending Physician St. Mary's Free Hospital for Children, Out-Door Department. Cloth. Pp. 169. Price, $1.25. Philadelphia and London: J. B. Lippincott Co. 1900.

Nettleship on the Eye. New Edition. Diseases of the Eye, by Edward Nettleship, F.R.C.S., Ophthalmic Surgeon at St. Thomas' Hospital, London; Surgeon to the Royal London Ophthalmic Hospital, Etc. New (6th) American from the Sixth English Edition, Thoroughly Revised by William Campbell Posey, M.D. With a Supplement on the Detection of Color Blindness by William Thomson, M.D., Professor of Ophthalmology in the Jefferson Medical College, Philadelphia. Just Ready. In One 12mo Volume of 562 Pages, with 192 Illustrations. Selections from Snellen's Test-Types and Formulæ, and 5 Colored Plates. Cloth, $2.25, net. Philadelphia and New York: Lea Brothers & Co.

Fractures. By Carl Beck, M.D., Visiting Surgeon to St. Mark's Hospital. With an Appendix on the Practical Use of the Röntgen Rays. 178 Illustrations. Cloth. Pp. 335. Price, $3.50. Philadelphia: W. B. Saunders & Co. 1900.

A Manual of Medicine. Edited by W. H. Allchin, M.D., F.R.C.P., F.R.S.E., Senior Physician and Lecturer on Clinical Medicine, Westminster Hospital. Vol. i. General Diseases, Diseases Excited by Atmospheric Influences, the Infections. Cloth. Pp. 442. Price, $2. New York: MacMillan & Co. 1900.

Vivisection. Hearing Before the Senate Committee of the District of Columbia, Feb. 21, 1900, on the Bill (S. 34) for the Further Prevention of Cruelty to Animals in the District of Columbia. Cloth. Pp. 223. Washington. Government Printing Office. 1900.

King's Manual of Obstetrics.—New (8th) Edition. A Manual of Obstetrics. By A. F. A. King, M.D., Professor of Obstetrics and Diseases of Women in the Medical Department of the Columbian University, Washington, D.C., and in the University of Vermont, etc. In One 12mo. Volume of 612 Pages, with 264 Illustrations. Cloth, $2.50, net. Philadelphia and New York: Lea Brothers & Co.

Normal Histology. By Edward K. Dunham, M.D., Professor of General Pathology, Bacteriology, and Hygiene, in the University of Bellevue Hospital Medical College, New York. New (2d) Edition. In One Very Handsome Octavo Volume of 319 Pages, with 244 Illustrations. Cloth, $2.50, net. Philadelphia and New York. Lea Brothers & Co.

Progressive Medicine—Volume ii, 1900. A Quarterly Digest of Advances, Discoveries and Improvements in the Medical and Surgical Sciences. Edited by Hobart Amory Hare, M.D., Professor of Therapeutics and Materia Medica in Jefferson Medical College of Philadelphia. Octavo, Handsomely Bound in Cloth, 401 Pages, with 81 Engravings. Philadelphia and New York: Lea Brothers & Co.

The Cell in Development and Inheritance. By Edmund B. Wilson, Ph.D., Professor of Zoology, Columbia University. Second Edition, Revised and Enlarged. Cloth. Pp. 485. Price, $3.50. New York: The MacMillan Co. 1900.

University of Pennyslvania. Contributions from the William Pepper Laboratory of Clinical Medicine. Paper. Pp. 477. Philadelphia: Press of Wm. F. Fell & Co. 1900.

Medical and Surgical Report of Presbyteran Hospital in the City of New York. Volume iv. January, 1900. Edited by Andrew J. McCosh, M.D., and W. Gilman Thompson, M.D. Paper. Pp. 223. New York: Trow Directory Printing and Bookbinding Co. 1900.

Stimson's Operative Surgery. A Manual of Operative Surgery, by Lewis A. Stimson, B.A., M.D., Professor of Surgery in Cornell University Medical College. New (4th) and Thoroughly Revised Edition. In One Royal 12mo. Volume of 581 Pages with 293 Illustrations. Cloth, $3, net. Philadelphia and New York. Lea Brothers & Co.

On Neuro and Neuro-Fibromatosis. By Alexis Thomson, Fellow of Royal College of Surgeons of Edinburgh. Cloth. Pp. 167. Edinburgh: Turnbull & Spears. 1900.

Suggestions to Medical Writers. By George M. Gould, A.M., M.D. Cloth. Pp. 185. Price, $1.25. Philadelphia: Philadelphia Medical Publishing Co. 1900.

Food for the Sick and How to Prepare It. With a Chapter on Food for the Baby. By Edwin Charles French, M.D. Cloth. Pp. 171. Price, $1. Louisville, Ky.: John P. Morton & Co. 1900.

PAMPHLETS.

American Public Health Association. Lomb Prize Essay, 1886. Disinfection and Individual Prophylaxis Against Infectious Diseases. Revised in December, 1899, by the Author. By George M. Sternberg, M.D., L.L.D., Surgeon-General U. S. Army. Paper. Pp. 45. Columbus, Ohio: Berlin Printing Co. 1900.

Annual Report of the Board of Health of the City of Davenport, Iowa, Year Ending March 1, 1900. Paper. Pp. 24.

The Bubonic Plague. By Walter Wyman, Surgeon-General Marine-Hospital Service. Paper. Pp. 50. Washington: Government Printing Office. 1900.

Case of Foreign Body Passing Directly Through the Eye and Lodging in the Fatty Tissue in the Posterior Portion of the Orbit—Dislocation of Lens—Recovery—Case of Foreign Body in the Lens—Cataract—Iridectomy—Removal of Steel with Magnet—Removal of Lens—Intraocular Hemorrhages—Evacuation of Hemorrhages—Good Result. By Frank Allport, M.D., Chicago. Reprinted from Ophthalmic Record.

Criminal Abortion: Its Evils and Sad Consequences. Carcinoma on the Floor of the Pelvis. Microscopical Studies in Pelvic Peritonitis. A Hitherto Undescribed Disease of the Ovary; Endothelioma Changing to Angioma and Hematoma. Another Hitherto Undescribed Disease of the Ovaries; Anomalous Menstrual Bodies. The Third Hitherto Undescribed Disease of Ovary: Myxomatous Degeneration. The Fourth Hitherto Undescribed Disease of Ovary: Colloid Degeneration. Diagnosis and Some of the Clinical Aspects of Gyroma and Endothelioma of Ovary. By Mary A. Dixon Jones, M.D., F.R.M.S. Reprints.

Gastrostomy for Traumatic Stricture of Esophagus—Report of Case—Treatment of Cancer of Cervix of the Uterus Complicated by Pregnancy. By George Ben Johnston, M.D., Richmond, Va. Reprints.

Hemorrhage and Circulatory Disturbances in Complicated Fracture; Management of Large Congenital Exomphalos—Infantile, Radical or Tentative Treatment of Piles, and Therapy of Feminine Hernia in the Adult. By Thomas H. Manley, M.D., New York. Reprints.

A Modern Study of Gouty and Rheumatic Manifestations. Translated from the French. Revised Second Edition by Edmond L. Gros, M.D., of the Faculty of Paris. Paper. Pp. 23.

Medical Legislation in Nebraska. By H. Winnett Orr, M.D., Lincoln, Neb. Reprinted from Western Medical Review.

New Instrument.

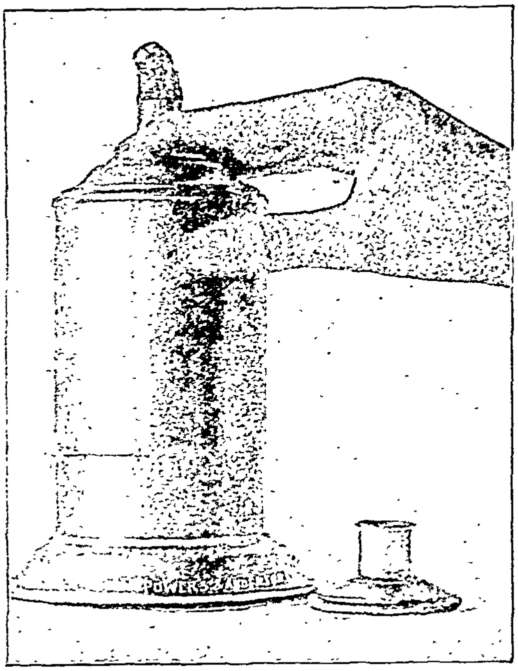
An Aseptic Soap-Container.

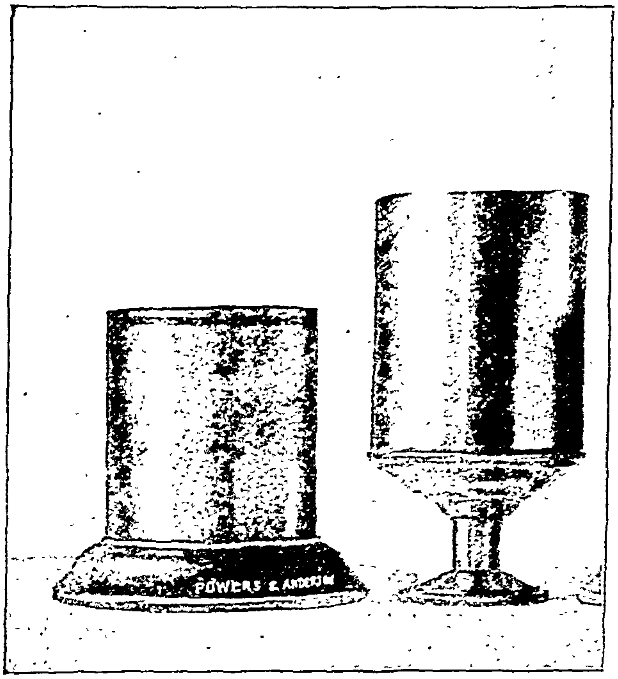
STUART McGUIRE, M.D.

SURGEON IN CHARGE OF ST. LUKE'S HOSPITAL, RICHMOND, VA.

In my personal observation in several leading hospitals, where surgical cleanliness was often carried to the point of sterilizing iodoform and protecting the hands with rubber gloves, I have failed to note a single instance in which an effort was made to eliminate the possibility of infection from the soap-dish; on the contrary, the universal practice was to have an open jar or bowl of green soap on the washstand, into which the operator, assistants and nurses freely inserted hands soiled from routine work or septic from an operation just completed.

Green soap is readily infected with micro-organisms, particularly those of a pyogenic nature, and the practice referred to was so repugnant to the writer's surgical conscience that he has made repeated but unsuccessful efforts to find a soap-container on the market which would correct the evil. With the aid of Powers & Anderson, instrument makers, of Richmond, Va., he has lately perfected a simple device which, after practical use, has proved eminently satisfactory.





It is made of metal, nickel-plated, and consists of a base or piston, a cup or barrel, and a cap or stopper. The method of operation can be seen by a glance at the accompanying cut. After the container has been filled with soap, it is placed in the sterilizer and subjected to germicidal heat for an hour. When required for use the cap is removed and downward pressure causes the soap to protrude through the opening in the top. The apparatus, as at present manufactured, is 6½ inches in extreme height, and 3 inches in diameter. It is clean, economical and durable.

Societies.

Santa Clara County Medical Society.—At the meeting of this Society, held in San Jose, Cal., June 20, the following officers were elected: president, J. F. Burns; first vice-president, G. F. Witter; second vice-president, R. W. Payne; treasurer, A. Jayet; secretary, F. La Spada.

Santa Fe Medical and Surgical Society.—This Society met in Topeka, Kan., June 29. The following officers were elected: president, C. A. McQuire, Topeka, Kan.; first vice-president, W. R. Priest, Concordia, Kan.; second vice-president, J. J. Schuler, Raton, N. M.; third vice-president, H. E. Hastings, Olathe, Kan.; fourth vice-president, G. W. Miel, Denver, Colo.; secretary and treasurer, J. D. Freeman, Topeka, Kan. The next meeting will be held in Denver, Colo., Sept. 26, 1900.

The Mississippi Valley Medical Association will hold its twenty-sixth annual meeting at Asheville, N. C., on October 9, 10 and 11, under the presidency of Dr. H. N. Moyer, of Chicago. The annual address in medicine will be delivered by Dr. I. N. Love, of St. Louis; that in surgery by Dr. C. A. Wheaton, of St. Paul, Minn. A one-fare rate for the round trip is expected. The Secretary, Dr. Henry E. Tuley, 111 W. Kentucky St., Louisville, Ky., requests that titles of all papers be sent to him within thirty days.

California Northern District Medical Society.—At the recent meeting of this Society, held in Woodland, the following officers were elected: president, Wm. Ellery Briggs, Sacramento; first vice-president, C. W. Jones; second vice-president, E. W. Hanlon, Marysville; third vice-president, F. W. Carpenter, Grafton; secretary, Arthur Stone; treasurer, O. Stansbury, Chico.

Tri-State Medical Association.—This Association, the membership of which is taken from Maryland, West Virginia and Western Pennsylvania, met in Frostburg, Md., June 29. The officers elected were as follows: president, J. M. Miller, Romney, W. Va.; vice-presidents, W. O. McLane, Frostburg, Md.; F. H. Gump, Bedford, Pa.; K. Taylor, Slanesville, W. Va.; secretaries, Frederick W. Fochtman, Cumberland, Md.; Percival Lantz, Alaska, W. Va.; treasurer, H. W. Hodgson, Cumberland, Md. Thirty-five members were present.

Oregon State Medical Society.—This Society met in Portland for its twenty-seventh annual meeting, June 27. Dr. A. M. Phelps, of New York City, was present, read a paper and performed several operations before the society. The following officers were elected: president, W. E. Carll, Oregon City; vice-president, C. J. Smith, Pendleton; secretary, W. F. Amos, Portland; treasurer, Mae H. Cardwell, Portland. A resolution was passed requesting the legislature to create a State Board of Health. Twenty-six new members were added to the Society.

Omaha Medical Society.

Omaha, Neb., May 22, 1900.

STONE IN THE BLADDER.

Dr. B. B. Davis read a paper on this subject, in which he said that it has been held that an alkaline water-supply and climatic conditions are the chief causes of this condition; but, in his opinion, infection plays the same rôle as it does in the formation of gall-stone. As regards vesical calculi, it is more and more clear that the solid constituents of the urine can not form the nucleous unless preceded by germ action. The chief early symptom is sharp pain at the close of urination. The later symptoms are the occasional presence of blood in the urine, though blood-cells are found with the microscope when there is no gross evidence of blood; cystitis, often with pus in the urine; occasionally, small calculi; cutting pain is referred to a point one inch back of the meatus; the patient often thinks he has a stricture or an ulcer, this opinion being due to the location of the pain; fever, due to infection. The larger the stone the less the pain; and the more stones, the greater the pain; the presence of a large stone causes very frequent urination and exhausts the patient. One point, too often omitted, is the necessity of bimanual examination; in women through the vagina, and in men through the rectum. Theoretically, Bigelow's is the only operation for stone; but practically, the results of a large number of such operations have proved disappointing, for the reason that the operation requires special skill and dexterity. Surgeons in British India, where vesical calculus is very prevalent, use the Bigelow method for soft stone, and perineal or suprapubic cystotomy on those known to be hard.

The first case reported by the author, in 1887, was that of a girl 18 months old. Tenesmus had been noticed for 9 months. The early treatment had been directed toward the rectum, and she had been treated for prolapse and ulceration of the rectum. Dr. Davis dilated the urethra and removed a stone composed of urates, 2⅛ inches in circumference, weighing 75 grains. He was afraid that permanent incontinence would result, but it did not. The second case was that of a man 51 years of age, who, it was thought, had one large and a few small stones, but on operation, sixteen small uric-acid calculi were found, weighing ½ ounce. The third was that of a man of 74, who urinated every five to ten minutes, day and night; pus was present in abundance. A suprapubic operation was performed and the bladder drained through the perineum by a button-hole incision. After removing a phosphatic stone seven inches in circumference, weighing 3¼ ounces, the incision was closed. In the fourth case, that of a man 52 years of age, the same method was used, and a large, rough, jagged stone, composed of lime and mixed salts, 6½ inches in circumference and weighing 2¾ ounces was found in a diverticulum above the prostate. Although the surface of the stone was very rough, blood had been noticed in the urine only twice. He said that the operation is better done by the suprapubic method, especially if there is much infection and pus, with a thickened bladder wall. He has been much pleased with his results in closing the upper incision at once and draining through the perineum; the drainage is perfect and is continued until all cystitis had disappeared. Unless this is done, more calculi will be formed. Frequent irrigation through the drain is practiced. He uses urotropin in 10-gr. doses in a glass of water before meals, in all cases with infected urine, prior to any soundings or operation.

Dr. J. P. Lord said that median lithotomy needs more attention than has been given it, and that the suprapubic operation is very formidable for an old patient in bad condition. He is very much inclined to drain as suggested, and is pleased with Halsted's method of doing a suprapubic operation and then submerging the patient in a continuous bath till recovery.

Dr. J. E. Summers, Jr., was much impressed with the case of the baby, as such cases often mislead because the symptoms do not point in the right direction. He believed that Dr. Davis did the only feasible operation for the patient with the oxalate stone. When he began his surgical work, all the suprapubic patients died. He has done many lateral lithotomies as taught by Little, and heartily approves the closure of the suprapubic incision, and drainage through the perineum.

Dr. W. O. Bridges said that Dr. Davis was right in urging attention to greater care in diagnosis, as the symptoms are variable and many cases of stone are missed. He had seen many in which neither pain nor blood was present; one seen recently was that of a young man, a masturbator, who had dribbling of urine and wore a urinal. Previous diagnosis had been made of irritability due to masturbation, but he suspected stone and referred the patient to another physician, who found and removed one. Women often have stone without a single symptom except irritability of the bladder. In patients over 50 years of age, examination for stone should never be omitted.

Dr. W. O. Henry thoroughly approved the suprapubic operation with perineal gauze-wick drainage. He called attention to one symptom not mentioned, but important—the sudden arrest of the stream of urine when stone is present.

Dr. A. B. Somers spoke on the medical aspect of stone. He said that he knew of no drug that would dissolve stone in the bladder. He believed that bacteria are the cause, and that infection starts with the formation of the nucleus. There are few urinary antiseptics; boracic and benzoic acids are useful, but must be taken in large doses, at least 30 gr. in the twenty-four hours; the urine can thus be made acid, and pus kept down, as it thrives in alkaline urine only. Of late he has used urotropin in large doses with very good results.

Dr. B. B. Davis said, in answer to a question, that precipitation may occur in normal urine, but in aseptic urine it will be so slight that the precipitate will pass out; while it will become entangled in septic urine and cohere into a mass. He has never known of a suprapubic operation on a woman and can see no reason for it, except in case of encysted stone. He does not believe in catheter-drainage through the urethra, as it is too painful, neither does he approve of through-and-through drainage.

COMPLEX MALIGNANCY.

Dr. J. E. Summers, Jr., and Dr. Harold Gifford presented a patient on whom Dr. Summers had operated ten years ago, removing a sarcoma, lying over the parotid and adherent to the capsule, together with all the glands possible. There had been no recurrence. The dissection was very ample; the facial nerve had been cut, and the parotid tied. Recently Dr. Gifford had found a carcinoma of the limbus of the cornea, which he removed, making thorough cauterization. Still later, he had eviscerated the eye. The patient also had pulmonary tuberculosis.

Dr. B. B. Davis said that he was very glad to see such a case, as it was useful to counteract the feeling of depression which comes so often when we think of the results in operating on malignant cases.

Dr. **Harold Gifford** related the case of a patient with deep cancer of the face, on which he operated ten years ago. He knew he was compelled to leave some cells, but there had been no return. He also recalled a case of glioma of the retina, which he enucleated several years ago, and left large cells. He asked for permission to eviscerate, but was not allowed to do so. The child is still alive and well.

Dr. **W. R. Lavender** called attention to the fact that sarcoma spreads through the vessels; when the tumor is removed and the vessels are tied, there is no recurrence. Carcinoma spreads by the lymphatics, and infection easily takes place.

Kings County Medical Association.

New York City, June 12, 1900.

H. Arrowsmith, M.D., President.

POSTERIOR HYPERTROPHY OF THE MIDDLE TURBINATE.

Dr. **W. H. Steers** presented a specimen of this rather infrequent condition. The patient was 38 years of age, and of good personal history and habits. He had suffered for some time from nasal obstruction. Last January, while under treatment at an institute, a snare was broken off in his nose, and after this several severe hemorrhages occurred. On coming under observation, posterior rhinoscopy showed a round black mass projecting into the rhino-pharynx. After the free use of suprarenal extract, the tissues contracted sufficiently to show a piece of wire, and also some ulcerated spots. Considerable difficulty was experienced in removing the wire from the tissues in which it was imbedded, and when this was finally accomplished, there was such a severe hemorrhage that it was necessary to plug the nose. The hemorrhage recurred twice afterward, and it was not until the tenth day that the tampon could be permanently removed. Notwithstanding this, there was no sepsis, and the only untoward result was a small perforation of the cartilaginous septum. Five days later, there was a sudden recurrence of the bleeding, which terminated fatally. There was no history indicating that the man was a "bleeder."

MERCURIAL PYTALISM FROM INTRAUTERINE DOUCHING.

Dr. **T. R. Mansfield** reported the case of a woman who was confined March 18. When he saw her first—about ten days later—there was evidence of septicemia, and she was accordingly given a douche consisting of one gallon of a 1 to 4000 solution of mercury bichlorid. When seen two or three days later, there was excessive pytalism, with swelling of the gums. Mercury had not been used in any other form, and there had been perfect drainage.

Dr. **T. G. Baldwin** recalled a case in which he had seen pronounced mercurial poisoning, from irrigation with mercury bichlorid, in an operation for ovarian cyst. It was the only case that had come under his observation, but many others had been reported.

Dr. **E. H. Squibb** remarked that it was very easy for such tablets to become mixed, so that one might be unconsciously employing tablets of much greater strength than indicated by the label.

Dr. **Victor A. Robertson** recalled a fatal case of probable mercurial poisoning occurring in a case of abdominal section at the New York Hospital. It was in the days of the Lister spray and dressings, and bichlorid had been used very freely during the operation for the purpose of irrigating the uterus. The day following the operation the patient developed ptyalism and severe and uncontrollable diarrhea.

BRAIN DISEASE FOLLOWING MASTOIDITIS.

Dr. **W. S. Shattuck** reported two fatal cases. The first patient was 4 years of age, and had had chronic suppurative otitis media for two years. On January 15, a fluctuating tumor appeared over the mastoid on the affected side, having been preceded for six or eight weeks by severe and almost constant pain over the mastoid process and along the neighboring muscles. When seen by him, January 19, the canal was filled with thick and offensive pus, the tympanic membrane was nearly destroyed, and there was a large tumor over the mastoid. Operation was resorted to immediately, and revealed necrosis of the bone and an epidural abscess. As nothing pointed to the necessity for further exploration, the wound was packed. For three days, improvement was marked, but on the next day, the temperature began to rise again, and the child became irritable and suffered pain. On January 25, the patient became comatose, and died in a few hours. No autopsy was permitted. The second patient was a man 19 years of age, who was seen on Jan. 4, 1900. He had had for the past ten years a chronic middle-ear disease. On January 8, the temperature rose to 102 F., and there was a fulness in the ear. The man refused operation. He was not seen again until January 12, at which time mastoid tenderness, rapid pulse and elevation of temperature were present. An exploratory operation was done, but no epidural abscess was found. The temperature remained at about 102 F., and he died two or three days later. No autopsy was allowed.

Dr. **J. Scott Wood** said that both of these cases emphasized the desperate nature of this affection and the necessity for early and thorough operation. The second case showed how even a chronic case of very long standing might end fatally. If the patient had consented to the operation when it was first advised his life might have been saved. The mastoid operation is comparatively simple and can be done with but little risk. The fatalities following it are not usually attributable to the operation itself but to the fact that consent has been withheld too long.

Dr. **A. C. Brush** said it was peculiar how suddenly the symptoms would make their appearance in many cases of cerebral abscess which had been relatively slow in forming. This report reminded him of three cases of this kind, all of which terminated fatally. He had not met with a single case of this class in which recovery had taken place. This emphasizes the danger of these chronic suppurative processes of the middle ear. If operative treatment is not instituted until the abscess has formed, the prognosis is hopeless.

ANTITOXIN POISONING.

Dr. **George A. Treadwell** gave his personal experience as a patient. While attending a case of diphtheria, four years ago, he suddenly developed a severe angina, with membranous exudation. A culture was taken, but without waiting for the result, 1000 units of antitoxin were injected into the abdominal wall, and the next day another dose of the same amount. At the end of thirty-six hours there was temporary improvement, but by the eleventh day, he began to feel weak, and the heart's action was irregular. On the fourteenth day, an urticarial eruption developed all over the body, and pains were felt in the joints. To relieve the eruption, he took ten minims of Fowler's solution in two doses. The result of this was that the symptoms of arsenic poisoning were added to the others, one of the earliest being tetanic contraction of the muscles of mastication. The temperature at this time was 104 F., and movement difficult and extremely painful. There was a sudden fall of temperature, whereupon the pains in the lower extremities were relieved. Then severe diarrhea supervened, characterized by loose, black stools, although no medicine had been taken which should cause such darkening. At the time of the second injection his wife was given an immunizing dose of antitoxin. This was promptly followed by pains in the muscles and joints, and by an urticarial eruption. No diphtheria bacilli were found in her throat and her heart was not affected. It would seem therefore, that the symptoms in both cases were fairly attributable to the antitoxin. He referred to several other cases of antitoxin poisoning that had been reported, but added that in spite of this, his faith in antitoxin remained unshaken. That used in his case was furnished by the Brooklyn Board of Health, at a time when the manufacture of antitoxin was in a comparatively crude state.

Dr. **Louis C. Ager** emphasized the fact that great improvement has taken place in the manufacture of antitoxin in the past four years. He said it is quite generally conceded that the heart symptoms in these cases are due to the diphtheria rather than to the antitoxin, and that the cutaneous manifestations are due to the antitoxin, or to some accidental ingredient.

NERVE AND MUSCLE DEGENERATION DUE TO HIGH TENSION ELECTRIC CURRENTS.

DR. A. C. BRUSH reported two cases. The first was that of a woman, who, while attempting to get on a trolley-car on a rainy day, received a severe shock, and was unable to let go her hold on the brass rail. She remembered nothing more until she had recovered, but it was learned that she could not be released until the current was turned off. Following this, she suffered from headache, vertigo, pains in the limbs, and screaming attacks. Her circulation was poor, and there were ulcers on the right ankle. When examined Nov. 22, 1899, there was a decided loss of power in the right arm, and slight loss of power in the left leg. The faradic current produced no contraction in the right arm, and the response to the galvanic current was slow and very painful. The second case was that of a male, 50 years of age, who previous to Feb. 17, 1899, had been in good health, and accustomed to heavy work. On that day, the weather being wet, he received a shock while stepping on a trolley-car, and was unable to release himself until the current was turned off. Since that time, he has had loss of sensation in the lower limbs. The muscles are flaccid and show an absence of faradic response. Microscopic examination of the muscles from both of these cases showed swelling of the muscular fibers, dimness of the striæ, and the presence of fat granules and enlarged nuclei. These patients also presented hysterical manifestations due to the mental shock and fright associated with the accident, but it is evident that there was something more than hysteria, because of the occurrence of atrophy, the abnormal response to the electric current. and the results of microscopic study of the affected muscles. Without a history these cases would have been considered examples of multiple neuritis. Very high tension currents produce coagulation of cell constituents, and even though such a current is not employed on the trolley-wires, the prolonged application might more than counterbalance the moderate degree of tension.

REVISION OF THE UNITED STATES PHARMACOPEIA.

Dr. E. H. Squibb presented an outline of the work accomplished at the convention of 1900 for the revision of the United States Pharmacopeia. He said that, taking into consideration the distance covered by the representation, the attendance of delegates was remarkably good, but the presence of so few medical men was very striking and deplorable. He reported in full the recommendations of the president, Dr. Horatio C. Wood, who made the following suggestions, which were adopted: 1. That the business interests of the convention be divorced from the strictly scientific part of revision by the creation of a board of five trustees, the president of the convention and the chairman of the committee of revision being members *ex officio.* 2. That a constitution and by-laws be adopted, and the convention be made perpetual by incorporation. Dr. Wood was re-elected president, and a revision committee of twenty-five was elected. While it was not surprising that the business body should be made up wholly of well-known pharmacists, it was a matter of both surprise and regret that only six physicians were elected members of the revision committee. The convention adopted a complete constitution and set of by-laws, and directed that the organization shall be known and incorporated under the name of the United States Pharmacopeial Convention. The trustees are not to receive any compensation for their services, but such expenses as are incurred by their attendance at the meetings are to be paid from the funds of the convention. The chairman of the revision committee will be paid a proper salary for his services, and the members of the revision committee and outside experts employed are to be recompensed in accordance with the work accomplished.

A balance of $12,000 was turned over to the new Board of Trustees by the outgoing revision committee after all expenses had been paid. The funds accummulated during the past decade have come almost entirely from the sale of the Pharmacopeia, the publication of which was wisely retained in the hands of the committee.

As the convention was becoming unwieldly, it was resolved that the delegates in future should be selected only from the following organizations: Incorporative from medical colleges and medical schools connected with incorporated colleges and universities; colleges of pharmacy and pharmaceutical schools conected with incorporated universities; incorporated state medical associations: incorporated state pharmaceutical associations; theAMERICAN MEDICAL ASSOCIATION; the American Pharmaceutical Association, and the American Chemical Society, provided that each organization entitled to representation shall have been incorporated within, and in continuous operation in, the United States for at least five years before the time fixed for the decennial meeting of this convention. Further, it shall consist of delegates appointed by the surgeons-general of the United States Army, United States Navy, and United States Marine-Hospital Service.

The actual work of revision is to be largely conducted through circular correspondence—a plan which has been so effectively carried on for the past ten years by Charles Rice, Ph.D., who was re-elected chairman of the revision committee. It took two years to accomplish the last revision, but owing to the chairman's familiarity with the work to be done, this time may be shortened somewhat for the forthcoming book. He urged on the medical profession in general to take a greater interest in this standard book, and said he was confident that he voiced the wishes of the whole committee in stating that any recommendations would be gladly received and given due consideration.

For more detailed reference to the work of the committee on revision, see THE JOURNAL, vol. xxxiv, p. 1506.

Minnesota State Medical Society.

Thirty-second annual meeting, Duluth, June 27-29.

President Dr. Walter Courtney, Brainerd, in the chair.

VALUE OF THE NEWER SIGNS AS AIDS IN DIAGNOSIS.

DR. GEO. H. HEAD read a paper on the value of the newer signs and procedures as aids in diagnosis. He spoke more particularly of: 1. Koplik's spots in early diagnosis in measles; 2. Quincke's puncture in cerebrospinal meningitis; 3. Justus test in syphilis. In three hundred cases, 50 per cent. verified the test, there being a sudden fall in hemoglobin to 10 to 20 per cent. after giving mercury. In the primary stage the test was not definite, in the tertiary stage there was some reaction, but it was most definite in the secondary stage. It is not present in normal individuals. 4. Kernig's sign in cerebrospinal meningitis. In an analysis of 156 cases this test was positive in 84 per cent. It was not present in healthy individuals, but present in some brain lesions other than pure meningitis. 5. Litton's diaphragmatic phenonoma, which were present in a large percentage of healthy individuals, but absent in pleural effusions more especially. 6. Baginski's reflex in disease of the pyramidal tract; this reflex is the earliest to appear. He also spoke of the Widal reaction in typhoid fever; the leucocyte-count in all cases; the tuberculin reaction; eosinophilia in trichiniasis and the bacteriology of the blood and blood examinations. He urged greater care and more rigid examination of patients and that particular attention be paid to these new signs in diagnosis—for only in this way can the symptomatology of disease be verified.

EARLY DIAGNOSIS OF PULMONARY TUBERCULOSIS.

DR. JNO. W. BELL, Minneapolis, read a paper on this subject, in which he laid particular stress on the sum total of the symptoms, as no one symptom in itself was sufficient for a diagnosis; the tubercle bacilli being found often too late, and in some cases not at all. He spoke of the tuberculin reaction emphasizing the danger as routine.

DR. C. L. GREENE, St. Paul, spoke of the X-ray in incipient tuberculosis, saying that he used it as a routine measure in every suspicious case, and it had proved to be most satisfactory.

DR. CHARLES HUNTER, Minneapolis, said that the tuberculin reaction was most necessary in the early diagnosis of tuberculosis and was not dangerous.

ANTISTREPTOCOCCIC SERUM.

DR. CHARLES HUNTER, Minneapolis, in a paper on this subject reported that his cases had not proved favorable to the antistreptococcic serum, but that as all cocci have their own toxins, this may account for the negative results. The success attending the use of diphtheria antitoxin has demonstrated that serumtherapy is on the right track.

CARDIAC DILATATION.

Dr. A. N. Stinchfield, Rochester, read a paper in which he discussed the etiology, pathological changes, prognosis, diagnosis, and treatment, particular emphasis being laid on hard work, syphilis and alcohol as causal factors.

BACK TO MEDICINE.

Dr. A. F. Conley, Cannon Falls, in the above-mentioned paper, spoke of how internal medicine had been at a standpoint during the last ten years, great advances having been along surgical lines and in the specialties, and claimed that the profession at large was losing sight of the great field of internal medicine.

Dr. Charles Greene, St. Paul, said he disagreed with the author; that medicine had made and was making great advances, and cited the diphtheria antitoxin as an example.

Dr. Burnside Foster, St. Paul, reported cases of pemphigus which had come under his observation.

RABIES IN MINNESOTA.

Dr. F. F. Westbrook read a paper on this subject in the section on pathology, in which, after tracing the origin, causes and methods in arriving at a diagnosis, he said he had collected forty-six cases of rabies in the state, as follows: St. Paul, 13 cases, 8 positive; Minneapolis, 8 cases, 5 positive; Montevideo, 5 cases, 3 positive; etc. Four cases were observed in human beings, and 1 case each in a horse, sheep, pig and wolf. He concludes that rabies exists in the State of Minnesota, but that it is very widely distributed and not dangerous, and that there have been enough cases reported; that it should be recognized early.

PROPHYLAXIS OF OPHTHALMIA NEONATORUM.

Dr. Frank C. Todd, Minneapolis, read a paper in the section of diseases of children, on this subject, and said that with the single exception of atrophy of optic nerve this was the most frequent cause of blindness. He urged as a routine practice the use of the 2 per cent. silver nitrate solution as used originally by Credé. In conclusion he suggested the following rules: 1. Whenever possible and practicable the head should be delivered without puncturing the membrane. 2. In all suspicious cases born in public hospitals the Credé method, including the use of 2 per cent. silver nitrate solution, should be practiced. 3. In all cases, when the Credé method is not practiced, the eyelids and face should be mechanically cleansed with an aseptic solution, and one or two drops of a 5 per cent. protargol solution be dropped between the open lids. 4. When the disease appears in one eye, the other should be immediately protected by a shield, or, if this can not be procured at once, by any kind of a clean covering that will prevent infection of the well eye.

CHRONIC INDIGESTION.

Dr. C. A. Kelsey, Minneapolis, read a paper in which he dealt particularly with the causal factors, diagnosis and treatment of chronic indigestion. In the treatment, he laid special stress on nux vomica as a curative agent. In the discussion nearly every drug, together with lavage, was suggested as a remedy, but no definite conclusions were reached.

TREATMENT OF PENETRATING WOUNDS OF THE CHEST.

Dr. J. H. Dunn, Minneapolis, read a paper in the surgical section, on this subject, in which he considered stab and bullet wounds more especially. He said the great point in treatment was to know when to go ahead. In the vast majority of cases, after investigation, no treatment was required except fixing the side with adhesive plaster, absolute rest, and watchful expectancy. He deprecated most strongly the indiscriminate use of the probe, and mentioned how seldom foreign material, such as parts of the clothing, are found in such wounds.

Dr. Charles A. Wheaton, St. Paul, stated that the reason why foreign material was not found in the wound was because of the velocity of the bullet in case of gunshot wounds.

SIGNIFICANCE OF BLOOD-COUNT IN SURGICAL DIAGNOSIS.

Dr. A. J. Coey, Chicago, pointed out the great value of the blood-count as an aid in the diagnosis of surgical diseases and urged its more extensive employment. Blood examinations, when properly and systematically made, are of inestimable importance to the surgeon as an aid in differential diagnosis. Leucocytosis is as certain to be found in cases of inflammation and suppuration as are rapid pulse and high temperature in pneumonia. It has been stated that the uselessness of blood examinations is definitely proved, because occasionally an inflammatory condition exists without leucocytosis. Similarly, the practitioner might be expected to disregard the physical signs of pneumonia if the patient had a pulse of 80, a temperature of 98.4 F., and did not have rusty sputum. In cases of suppuration, the increase of white blood-corpuscles is proportionate to the intensity of the inflammation. As the inflammation disappears, there is a gradual diminution of the leucocytes which may be present in subnormal amount at the time of convalescence. In obscure suppuration and especially in pus collections in the peritoneal cavity, blood examination is of the greatest diagnostic value. In malignant disease, leucocytosis is usually observed. The absence of leucocytosis in uncomplicated cases is, therefore, indicative of typhoid fever, tubercular peritonitis, gall-stone or renal colic, intestinal obstruction, fecal impaction, neuralgia, etc. Appendicitis furnishes the most marked example of the value of the blood-count as regards the decision to operate or not to operate. Cases of purely catarrhal appendicitis rarely present a leucocytosis. Given a case of a patient with pain in the region of McBurney's point and a stationary or increasing leucocytosis, that case is one for imperative, immediate surgical interference, whether other symptoms and signs be present or absent. A steadily increasing leucocytosis must always be considered as a bad sign and as demanding prompt operation. In septicemia and pyemia the leucocyte count is about on a par with the count in appendicitis. Streptococci and staphyloocci may frequently be found in blood cultures in many forms of infection. In surgical diseases leucocytosis with a rise in temperature would exclude hysteria and mental worry. In osteomyelitis and all abscess formations, pure cold abscess alone excepted, there is always a high leucocytosis.

COMMISSION BUSINESS IN MEDICINE.

Dr. C. L. Greene, St. Paul, read a paper entitled "A Problem in Ethics," in which he spoke of the commercial spirit of the profession as progressing. He dealt more particularly with the "commission business" that exists between doctors, cited cases, and said he had numerous proofs in his possession of this condition which would involve some of the best known men in the profession. He then presented resolutions to the effect that a committee of five should be appointed from the state medical society to investigate this matter; that every case should be reported to this committee, the proof obtained, and that upon conviction such members should be expelled from all societies, local and state, and should be reported to the American Medical Association. In the discussion that followed everyone was most enthusiastic over the resolutions, but only one side was represented.

THE LYMPH NODE AS A FACTOR IN DIAGNOSIS.

Dr. Charles A. Wheaton, St. Paul, spoke of the lymphatic system as the custodian of the system in a great many diseases, comparing the lymphatic glands to the policeman. He dealt more especially with tubercular glands of the neck, deprecating their wholesale enucleation. He said in the past he had operated on a great many tubercular glands of the neck, but in the future such operations would be far less frequent. When it is decided to operate on a selected case, complete enucleation is the only surgical procedure. He also spoke of the glands of the axilla and neck in carcinoma of the breast and cited a case in which he had removed the breast and the glands of the axilla on one side, but four months later a recurrence of the tumor in the other breast took place with enlargement of the axillary glands and the glands on both sides of the neck. He decided that in this case, the breast and glands should not be removed, as the involvement was too extensive.

Dr. C. H. Mayo, Rochester, differed from Dr. Wheaton in his conservative operation for tubercular glands of the neck, saying he had operated on about 360 cases and that the results justified the procedure.

Dr. F. A. Dunsmoor, Minneapolis, also urged operative procedure, because of the liability of the glands to break down and also because of the unsightly appearance.

Dr. F. C. Davis, Minneapolis, spoke of the microscopical findings in the glands of axilla and neck in cancer of the breast.

Dr. Walter Courtney, Brainerd, read a paper on "The Value of the Two-Stage Method of Suprapubic Cystotomy in Selected Cases."

Dr. C. H. Mayo, Rochester, presented an article on "Varicose Veins of the Leg." He spoke of the causes, prophylaxis and surgical treatment in these cases, and reported the results of operations made by him.

At the business meeting the number of sections was reduced to three: 1, Surgical, J. W. Andrews, Mankato, chairman; 2, Practice of Medicine, T. A. Nippert, Minneapolis, chairman; and 3, State Medicine, Hygiene and Medical Jurisprudence, H. S. Fullerton, Minnesota Lake, chairman. Fifty-six new members were elected. St. Paul was selected as the next meeting place, in June, 1901, a few days before the meeting of the American Medical Association. Resolutions were presented by Dr. Taylor, of St. Paul, and adopted, recommending that tubercular patients be isolated and taken care of by the state, like those suffering from other contagious diseases.

The following officers were elected: president, Wm. Davis, St. Paul; first vice-president, H. B. Pritchard, Winona; second vice-president, Mary Whetstone, St. Paul; third vice-president, H. B. Allen, Cloquet; secretary, Thomas McDavitt, St. Paul; treasurer, R. J. Hill, Minneapolis; censors, F. A. Dunsmoor, Minneapolis, and Walter Courtney, Brainerd; delegate to Washington, to meeting of Commission on National Legislation of the American Medical Association, Arthur Sweeney, St. Paul, Minn.

Philadelphia Pathological Society.

June 28, 1900.

President Dr. F. A. Packard in the chair.

CIRRHOSIS OF LIVER.

The President presented a specimen of extreme cirrhosis of the liver. The patient was a man aged 86 years, who gave a history of having been addicted to the use of enormous quantities of bitters, largely composed of alcohol. The abdomen had been swollen, with edema of the lower extremities. The urine contained blood and casts and the lungs showed congestion. At the autopsy, the visceral layer of pleura contained white pearly bodies showing evidences of new adhesions, the stomach and duodenum were much congested. The liver was of the typical hob-nailed variety. Irregular bands of fibers were seen by the microscope. The blood-vessels were dilated; the gall-bladder was small and contained 15 gall-stones; the pancreas was fibrinous, one kidney was cystic; there were no changes in the pericardium.

Dr. David Riesman spoke of a patient with cirrhosis of the liver who had suffered from gastric hemorrhages. There had been no edema, and death ensued from pneumonia. In this case the pericardium was adherent.

Dr. Albert Woldert referred to a case seen at the Howard Hospital, in which all the classical symptoms of gall-stones had been present, with deep jaundice, pain in the right hypochondrium, gall-stone colic, etc. The patient went to another hospital and her ailment was thought to be gall-stone. She became steadily worse and an exploratory incision was made. The gall-bladder was normal in size and contained no gall-stone. It was found that she was suffering from Charcot's liver. The wound was closed. Her condition was believed hopeless, and she left the hospital, six weeks later, as she thought, to die. She commenced to improve, however; all jaundice disappeared, and two months later she was as well as ever.

The President said that he had seen the case. He could not help believing that there had been a small gall-stone or plug of mucus which had occluded the mouth of the common duct, and which possibly had been removed by increased peristalsis following the operation. He offered this as an explanation of the benefit which is sometimes seen to follow exploratory operations in such cases.

ENDOTHELIOMA OF LUNG.

Drs. W. E. Hughes and J. D. Steele presented a specimen of endothelioma of lung and retroperitoneal lymphatic glands. The patient, a woman 69 years of age, began to fail six months ago, and later edema of the lower extremities occurred. At times there was marked cyanosis. Dulness was present on the left side of the chest with crackling râles. On the right side evidences of tuberculosis were noticed. At the autopsy, the right lung was found to be studded with grey nodules with areas of caseation, and at the base of the left lung three nodules were found. An aneurysm of the thoracic aorta was discovered which during life had given rise to the dulness in this region. At the bifurcation of the abdominal aorta enlarged lymph-glands were found, which he did not believe were tuberculous. On microscopic examination, it was found that the growths were endotheliomatous. In his opinion, the primary seat of the disease had been in the apex of the right lung. The growths in the lungs were typically those of tuberculosis.

Dr. David Riesman spoke of a case in which there had been gradual emaciation with scattered areas of dulness over the chest. At the autopsy, carcinoma of the lung was found, certain areas of which had undergone caseation, and were tuberculous.

ABSCESS OF THE LIVER.

Dr. David Riesman reported the case of a Belgian, 52 years of age, who had been operated upon two years ago for an abdominal affection—probably appendicitis. In March of the present year he suffered from diarrhea with hemorrhages, but had not tenesmus. In April he had another attack, and was later admitted to the Philadelphia Hospital. The abdomen was enlarged and presented the shape of a flattened cylinder. Liver dulness began anteriorly in the fourth, and posteriorly in the ninth, interspace, and extended to the umbilicus and even to the left of this region. The diagnosis was made of abscess of liver or pyothorax. An aspirating needle was inserted in the seventh interspace and five pints of reddish-brown or chocolate-colored fluid withdrawn. The specific gravity of the fluid was 1037; it was sterile and had a neutral seaction, and contained crystals of hematoidin. No ferment seemed to be present, and the ameba coli could not be found. Through the kindness of Dr. Simon Flexner, he presented specimens of ameba coli obtained from a case of dysentery seen in the Philippine Islands. It was stained in the liver tissues by Mallory's latest stain of thionin.

Dr. F. A. Packard stated that there were no physical signs pathognomonic of abscess of liver. One which he regarded as very comman was the appearance of the abdomen, which usually was that of a flattened cylinder. He referred to a case of abscess of liver which he had seen several years ago, in which he had found in the pus certain reniform bodies with pale protoplasm and deeply staining nuclei. These bodies resembled protozoa, but he had never been able to determine their exact nature.

CARCINOMA OF PANCREAS.

Dr. W. E. Hughes presented two specimens of the liver and adjacent viscera. One was a carcinoma of the pancreas which caused occlusion of the biliary duct, the other was a carcinomatous change occurring in the duodenum, probably resulting from a duodenal ulcer. In both cases it was found on autopsy that very gentle pressure would cause the bile to flow from the common duct. Both patients had been deeply jaundiced. A gall-stone was present in one case. In the carcinomatous pancreas there had been no metastasis.

Dr. Giddings presented sections from the head and tail of the pancreas. The absolute condition was not quite clear.

AMERICAN.

1. **Exudative Peritonitis.**—Berg concludes from the data which he has at his command that bacilli alone, except when in very large quantities, are not sufficient to produce exudative peritonitis. This immunity of the healthy peritoneum to the deleterious action of bacteria is due to its very rapid resorptive power, and this resorption, under normal conditions, is mainly by way of the blood-vessels, and is an active, and not a passive cellular process. It is manifested in the diseased as well as the healthy condition, but in somewhat lessened degree. The more marked the disease, the greater the interference with this activity; it is least when the peritoneal epithelium has been considerably altered, and ceases altogether with the destruction of these cells. These conclusions are of importance in connection with the question of drainage of the peritoneal cavity. By virtue of its rapid resorptive power, primary bacterial peritonitis is not a possibility unless the bacteria are present in such numbers as to paralyze the peritoneal cells and hinder resorption. There must be some factor interfering with the cellular activity of the cells favoring a sedimentation of the bacteria with their consequent further growth and development. These factors may be mechanical, such as gauze packing or drainage-tubes, etc., or chemical, either organic or inorganic in character. He gives his theory as to the character of peritonitis and the element of toxemia or absorption of bacterial toxins on which the severity of the case depends. These toxins should be treated by neutralization, using the chief excretory channels—the kidneys. This is accomplished best by frequent infusions of saline material into the circulation. If bacteriemia as well as toxemia exists, therapeutic procedures are of little value, and he has had but little good from bactericidal sera in these cases. In the treatment of exudative peritonitis *per se*, the chief aim should be to injure the organs as little as possible, but when the trouble is the direct result of a local disease, like appendicitis, an operation must be made to remove the cause. He thinks the use of soft mops for removing the exudate is the best method, except when large masses of fibrin are present, which can be washed out, or when the exudate is of a thick, creamy consistency and spread out among the intestinal coils in all directions. In these cases, irrigation is better than mopping. As long as the peritoneum is functionally active, drainage is superfluous and objectionable. When, however, the resorptive powers of a region are lost, then this part of the area must be drained. He believes that there is less danger from early catharsis than there is from absorption of toxins due to stagnation, and that when the indications of intestinal distension are manifested, catharsis should be employed as soon as possible. He recapitulates the plan of treatment that has given him the best results as follows: Celiotomy, the site of the incision depending on the cause of the peritonitis; removal of the acting cause; if the intestine is very much distended, incision of one of the most distended coils and evacuation of its contents; suture of the bowel if its muscular wall is not paralyzed, otherwise drainage of the proximal end of the bowel; removal of the exudate from the free peritoneal cavity by moist sponges; protection of all raw spaces or modified peritoneal surfaces by gauze; closure of the rest of the abdominal wound; in addition the general systemic treatment for the toxemia and bacteriemia, as outlined in the paper.

2. **Treatment of Typhoid.**—The indications for treatment given by English are: 1. To empty the gut of all infected matters as soon as possible; for this, he prefers calomel. 2. To render it as nearly as possible uninhabitable by microbes. While intestinal rest is highly desirable, the bowels may be moved once or twice every twenty-four hours, and for this he uses podophyllin, which increases the flow of bile and thus promotes intestinal antisepsis, the bile being the natural antiseptic. 3. To keep the intestines as aseptic as possible, his favorite drug for this being carbolated camphor. He takes 1 ounce of carbolic acid and 3 ounces of camphor gum, allows it to stand for a short time, and keeps it in an air-tight vessel, adding a little camphor to keep it from evaporating. He gives this in 10 and 12 drop doses every two hours for forty-eight hours, until there is some change in the color of the urine, and then diminishes the dose, but does not entirely discontinue it until advanced convalescence. 4. To neutralize the absorbed poison and to expel it from the body, water is the best agent, as large and frequent draughts of sterile water have a diluent, a diuretic and a diaphoretic effect. 5. To keep the temperature down, he has employed the following formula, given every one or two hours for five or six doses:

℞. Acetanilid ....gr. iii
Camphoræ monobrom.
Caffeinæ citratis, āā.....................gr. ss
M. Sig. At a dose.

In order to prevent over-action of the intestines and the heart and promote physiologic rest, he keeps the patient quiet and gives turpentin, if another remedy than carbolated camphor seems indicated. If it becomes necessary to check the bowels, which is seldom the case, he uses small doses of Dover's powder. When the pulse is rapid and soft, small doses of tincture of digitalis, about 5 minims in a dram of whisky, may be given every twenty-four hours. This should be used with care, however, in the early stages. The patient should use a bed-pan and urinal and be cautious about moving a muscle unnecessarily. 7. To support the strength of the patient, he thinks dissolved beef made after the Weir Mitchell formula is valuable.

℞. Acidi hydroclor,, c. p.........................ʒi
Aquæ dest., ad..............................℥i
M. Sig. One teaspoonful to a pint of water for making beef tea.

To prepare the beef for the patient, put one pint of boiled water, a good pinch of salt, and a teaspoonful of the above prescription in a one-quart glass fruit-jar, and shake well. Then add one pound of finely chopped beef, and shake again. Close the jar air-tight and set it in a cool place like the cellar floor, but not on ice, for twelve hours. Then put the jar into water and keep it warm, about 110 F. to 120 F., for four or five hours. Be careful not to let it get too hot. The contents of the jar should be strained through a cloth, and all the liquid squeezed out; the residue will be about the size of a hen's egg and nearly white. This essence may be seasoned with pepper and salt and given warm in ounce doses every hour or two during the second week. If the essence is properly made, the residue will be found to consist almost entirely of white fibrous matter, the red muscular fibers having dissolved out. During the third week, he adds milk by the pint every twenty-four hours in divided doses, largely diluted with sterile water and with as much salt as is palatable. He also gives the white of an egg in water with the juice of a lemon every twenty-four hours, and carbolated camphor in 6-minim doses four times a day, until the patient is entirely well.

3.—See abstract in THE JOURNAL of June 23, p. 1627.

6. **Questions of the Day in Medicine.**—The chief questions referred to in Da Costa's address are the numerous ones that come up in connection with the science of bacteriology, the possibilities of serumtherapy, etc. The active, general practitioner of medicine can not be a thorough bacteriologist, hence the importance of accessible laboratories. These he thinks will be useful if they can be attached to the colleges and hospitals, and besides giving instruction, can aid the profession in the necessary bacterial and chemical examinations required in the daily work. Another point is that of the transmission of malaria, and still another, the eradication of consumption, in which he pleads for the founding of sanatoria for the consumptive poor. The last subject which he discusses is that of medical education, and he shows how some of the needs are being met by changing the educational courses of our institutions.

8. **Hospitals for Consumptive Poor.**—According to Otis, the consumptive hospital should not be merely a place where those afflicted with the disease can die comfortably, but where they can receive treatment. He calls attention to the danger of contagion, and thinks that we must convince the public of the following facts: "1. That consumption is the most prevalent and destructive disease existing to-day, causing one-seventh of all the deaths, and is worst where human beings are crowded together—i. e., in the cities. 2. That it is communicable by the dried sputum, and hence, if this is not properly disposed of, there is danger to those constantly with the sick, and to the public. 3. That it is very curable in the early stages and may be arrested in any stage, hence the importance of proper treatment, and the need of special hospitals and sanatoriums where such treatment can best be instituted. 4. A certain proportion of consumptives will not safely dispose of the sputum, and should be transferred to a consumptive hospital for their own protection and that of the public. 5. Many cases of consumption appointed to die—the hopeless ones among the poor—have no decent place or care, and must either die in abject neglect or go to the almshouse. For this large class, consumptive hospitals are most urgently needed. The condition in which some of these dying consumptives are found is pitiable in the extreme." When the public fully realizes the truth of these facts, it will demand municipal and state aid for the care of the consumptive. In addition to the consumptive hospitals in cities, he thinks there should be state sanatoriums for open-air treatment, where the more hopeful cases may receive care. He believes that the expense of establishing these hospitals would be more than paid for by the preservation of many lives with their future of work still before them.

9. **New Pathogenic Mould.**—Ophüls and Moffitt describe a case in which there was chill; pleuritic effusion; fever to 104 F. and above; diazo but no Widal reaction; joint disorders; gland inflammation; cough; mucopurulent, occasionally blood-stained sputum; irregular consolidation of the lungs; no tubercle bacilli; sweating, etc. The diagnosis was septico-pyemia, and the patient died. The autopsy showed nodular consolidation and necrosis of the right lung; acute bronchopneumonia and chronic interstitial pneumonia with an abscess in the other lung; pus infiltration of the pillars of the diaphragm; necrosis and abscess in the retroperitoneal lymph-glands; empyema of the left pleura; enlarged and softened spleen; cloudy swelling and fatty infiltration of the liver; purulent osteitis and periostitis in the frontal bone over the left eye and in the upper part of the left tibia, and suppuration of joints. Microscopic sections showed nodules with necrotic centers in the liver. In all the diseased parts, peculiar parasitic organisms were found, which, in a few similar cases on record, have been described as protozoa. They seem to be a protozoan-like form of fungus, showing small spherical lumps of protoplasm enveloped in a highly refractile capsulating membrane which grows to 30 microns in diameter, and after reaching this stage breaks up into hundreds or more spore-like bodies which are highly refractile and stain well with anilin dyes. The capsule may burst and discharge these spores into the surrounding area, forming new parasites, or they may develop inside the capsule, which bursts later and sets them free. No locomotion has been observed, but on account of the very close resemblance to coccidia these organisms have been considered protozoans. They report experiments in which they were able to develop mold by cultures and from which they made inoculation experiments, showing the identity of the mold with the above organisms, which appear to be a form of its fructification. The mycelia forms develop only when free in the culture medium, and the protozoan-like bodies did not there develop.

10. **Typhoid Fever.**—The study of twenty-four cases, including 17 of perforation, 2 of pre-perforative necrotic areas, 1 of rupture of the mesenteric glands, and 3 with cause of symptoms undetermined is, for its extent, very thorough and elaborate. The conclusions given somewhat briefly are, that in many who are very sick, typhoid perforation or peritoneal infection can not be diagnosed until the results are wide-spread and fatal; and the chances for relief by operation are practically hopeless. In mild typhoids of fair general condition, an abdominal operation is readily borne, provided no peritoneal infection exists. A small number of typhoidal cases may have sudden perforation with free extravasation and fulminant, but largely localized symptoms; and in these operations must be done in from one to five hours before general infection has become past relief. Walling off of the perforation by adhesions is so rare that it is not to be counted upon. In mild cases, beginning infection, whether from perforation or otherwise, is accompanied with apparently slight symptoms—pains, tenderness, spasm and leucocytosis. The severe following symptoms mean general peritonitis, and call for serious consideration and study, but in most cases are either not rightly understood or not acted upon. Complaint of abdominal pain in case of typhoid should always arouse suspicion of peritoneal infection. Frequent leucocytosis counts are needed in every case, and an hourly count when abdominal pain is present. Pain, with local tenderness, muscular spasm and rising white-blood count point to operation in most cases, and always to surgical consultation. In this series of cases, operation was imperative for hours before it was done.

11. **Separation of Epiphysis of Olecranon.**—Cotton reports two cases of this alleged rare condition, in both of which it occurred apparently from muscular action alone, and union took place within a reasonable time under treatment. Skiagraphic diagnosis in both cases was employed, and the findings point to the fact that there is more than one form of this epiphysis, a thin scale-like form, and another thicker one of the ordinary type.

12. **Influenza in Children.**—Sheffield has treated quite a number of cases of epidemic and sporadic influenza in young children, and he finds that differentiation between the respiratory disturbances of la grippe and ordinary pneumonia is hardly possible at the outset of the attack. In young infants, dyspnea and cyanosis are not uncommon; the digestive organs are almost invariably implicated, anorexia and vomiting being pronounced. The early nervous symptoms are due largely to involvement of the Eustachian canal and frontal sinus, causing headache and earache, while extension of trouble toward the brain may produce serious complications like meningitis. The characteristic nervous symptoms in the order of their frequency, are hyperesthesia, somnolence, insomnia, and vertigo; the latter mostly escapes notice in very young children, though it shows itself by their drooping and swaying the head in various directions. The disease begins with an abrupt rise in temperature of three to five degrees and declines after a few days by lysis or crisis. Prostration is invariably present, even when other symptoms are masked, and of the other numerous complications, he mentions as especially common, pneumonia and meningitis. He also remarks in regard to nephritis and mentions a case. He finds no reference elsewhere to cardiac neuroses of la grippe in children, but reports a case of bradycardia as being of interest. Other complications are rheumatism, which is rare, adenitis, cutaneous eruptions, otitis, rhinitis, conjunctivitis, and periostitis. The diagnosis is easy during an epidemic, but for sporadic cases he relies chiefly on the presence of the Pfeiffer bacillus in the expectoration, the simultaneous development of respiratory, digestive and, at

times, nervous phenomena and excessive and early prostration. He has lost but 2 children out of 119, and says that the death-rate is often overestimated, the mortality being at least lower in children than in adults. As regards treatment, he insists on isolation and hygienic rules. The active treatment is chiefly symptomatic; and among the drugs, he especially mentions sodium benzoate as having a stimulating effect and being a remedial agent capable of meeting most if not all the indications. When called on to treat a case of la grippe of moderate severity he orders:

℞. Sodii benzoat.
Salol
Acetanilid, āā........................gr. iss
Caffein ....gr. ¼

M. Make one powder. Sig. One powder every three hours to a child 6 years old. If the pain is severe, and the child is kept awake, add one-twelfth grain of codein sulphate to each powder.

In cases where children refuse to take powders, he prescribes the following mixture, again adding codein, if necessary.

℞. Sodii benzoat.
Antipyrin, āā..........................ʒss
Liq. ammon. anisat.
Syr. scillæ comp., āā....................ʒii
Syr. altheæ............................℥iss
Aquæ anisi, q. s. ad.....................℥ii

M. Sig. One dram every three hours to a child 6 years old.

Along with this he always directs the inhalation of vapor of compound tincture of benzoin, one tablespoonful of tincture to a quart of boiling water to be kept constantly over a gas or alcohol stove during the entire sickness. For prostration, he thinks small doses of strychnin sulphate and diverse ammonia preparations are most useful. He attributes his success to the use of sodium benzoate and the observance of these other points.

13. **Rectal Valves.**—Bodenhamer's paper is an argumentative one, in which he endeavors to show that the so-called rectal valves do not exist and that the only thing resembling them are the normal lacunæ or sacculi, which have long been known. The alleged valves can have no necessary function, and he doubts that they exist.

15. **Formalin.**—Crawford advocates the use of formalin as an antiseptic in general surgery, but thinks that it has sometimes been used too strong. He gives tables showing the formalin percentage in antiseptic solutions of various strengths He prefers the use of a 4 per cent. solution as convenient for dilution.

17. **Laryngeal Manifestations of Typhoid Fever.**—The different laryngeal lesions mentioned by Lockard are specific typhoid ulcers, non-specific ones, necrotic lesions, submucous laryngitis, purulent perichondritis, diphtheria, and paralysis and spasms of the cords. He thinks we should make careful examinations for these complications in every case of typhoid, not only during the active stage but also during the entire period of convalescence.

18. **Atrophic Rhinitis.**—McKinney reports two cases which he thinks illustrate and confirm very decidedly the view of Bosworth, that atrophic rhinitis is a sequel to chronic purulent rhinitis of childhood. The patients were boys, 9 and 7 years of age, in whom there was evidence remaining of a purulent discharge, together with an existing advanced atrophy of the turbinated bone. There are other cases where he has had the atrophy but has never before witnessed the transformation stage in this form.

20.—Ibid.

21.—Ibid.

22.—Ibid.

23. **Frenkel Treatment of Tabes.**—Wolfstein describes the general principles of Frenkel's treatment, which has been noticed in detail in earlier articles in THE JOURNAL. The object of this paper is to popularize the method, which he thinks is a valuable one.

24. **Hemorrhoids.**—Monroe describes the different methods of treatment of hemorrhoids and apparently favors the clamp, though he does not think it will be as generally and universally used as the ligature.

26. **Management of Pregnancy and Myoma.**—From a study of his cases, some of which are reported here, Skene classifies myofibromata in the uterus in relation with child-bearing as follows: 1. Subcutaneous tumors, large or small, cause sterility as a rule. 2. Small subperitoneal myofibromata do not always cause sterility or dangerous complications. 3. Interstitial tumors, unless so small that they can not be detected, and large superitoneal tumors closely connected with the muscular tissues of the uterus, do not always cause sterility, but are most dangerous complications of gestation because they predispose to miscarriage and render delivery always difficult and dangerous, and often impossible. The first class may be left out of the account. The second requires attention in the first months to keep the uterus in position and aid in its rising from the pelvis. Help may be required in delivery and special protection from post-partum hemorrhage. The third demands hysterectomy as the surest means of safety. The time of operation is discussed, and he thinks that it should be undertaken only when there is evidence that the product of conception is no longer living.

27. **Intestinal Anastomosis.**—Ferguson describes a new form of enterotome as an aid in suturing the intestines, and gives a tabulated statement of a number of experimental operations showing its advantages for intestinal anastomosis.

29. **Placental Transmission.**—The author reviews the literature of placental transmission of drugs and specific disease, and finds that, while many drugs have no noticeable effect on the fetus, there are certain ones which have a special tendency to transverse the placenta and others that have a decided influence for good or evil. Maternal medication is therefore indicated in certain conditions, either to prevent the development of a similar condition in the fetus or to counteract the effect of germs or toxins already introduced. The drugs that have been found to affect the fetus *in utero* are notably opium, mercury, copper, lead, arsenic, and the iodids. Any morbific influence on the mother will react deleteriously on the product of conception, and either destroy it or render it feeble and less resistant to subsequent and post-natal invasion, or the disease will run an atypical course *in utero* with or without apparent vestiges at birth. The entrance into the fetal structure is accomplished through the fetoplacental circulation. Bacterial action probably renders the placental villi less resistant. As a rule, the infectious diseases do not manifest their characteristic visceral
in the fetus, probably because of the passivity
during antenatal existence. The germs,

6. **Questions of the Day in Medicine.**—The chief questions referred to in Da Costa's address are the numerous ones that come up in connection with the science of bacteriology, the possibilities of serumtherapy, etc. The active, general practitioner of medicine can not be a thorough bacteriologist, hence the importance of accessible laboratories. These he thinks will be useful if they can be attached to the colleges and hospitals, and besides giving instruction, can aid the profession in the necessary bacterial and chemical examinations required in the daily work. Another point is that of the transmission of malaria, and still another, the eradication of consumption, in which he pleads for the founding of sanatoria for the consumptive poor. The last subject which he discusses is that of medical education, and he shows how some of the needs are being met by changing the educational courses of our institutions.

8. **Hospitals for Consumptive Poor.**—According to Otis, the consumptive hospital should not be merely a place where those afflicted with the disease can die comfortably, but where they can receive treatment. He calls attention to the danger of contagion, and thinks that we must convince the public of the following facts: "1. That consumption is the most prevalent and destructive disease existing to-day, causing one-seventh of all the deaths, and is worst where human beings are crowded together—i. e., in the cities. 2. That it is communicable by the dried sputum, and hence, if this is not properly disposed of, there is danger to those constantly with the sick, and to the public. 3. That it is very curable in the early stages and may be arrested in any stage, hence the importance of proper treatment, and the need of special hospitals and sanatoriums where such treatment can best be instituted. 4. A certain proportion of consumptives will not safely dispose of the sputum, and should be transferred to a consumptive hospital for their own protection and that of the public. 5. Many cases of consumption appointed to die—the hopeless ones among the poor—have no decent place or care, and must either die in abject neglect or go to the almshouse. For this large class, consumptive hospitals are most urgently needed. The condition in which some of these dying consumptives are found is pitiable in the extreme." When the public fully realizes the truth of these facts, it will demand municipal and state aid for the care of the consumptive. In addition to the consumptive hospitals in cities, he thinks there should be state sanatoriums for open-air treatment, where the more hopeful cases may receive care. He believes that the expense of establishing these hospitals would be more than paid for by the preservation of many lives with their future of work still before them.

9. **New Pathogenic Mould.**—Ophüls and Moffitt describe a case in which there was chill; pleuritic effusion; fever to 104 F. and above; diazo but no Widal reaction; joint disorders; gland inflammation; cough; mucopurulent, occasionally blood-stained sputum; irregular consolidation of the lungs; no tubercle bacilli; sweating, etc. The diagnosis was septico-pyemia, and the patient died. 29. **Placental Transmission.**—The author reviews the literature of placental transmission of drugs and specific disease, and finds that, while many drugs have no noticeable effect on the fetus, there are certain ones which have a special tendency to transverse the placenta and others that have a decided influence for good or evil. Maternal medication is therefore indicated in certain conditions, either to prevent the development of a similar condition in the fetus or to counteract the effect of germs or toxins already introduced. The drugs that have been found to affect the fetus *in utero* are notably opium, mercury, copper, lead, arsenic, and the iodids. Any morbific influence on the mother will react deleteriously on the product of conception, and either destroy it or render it feeble and less resistant to subsequent and post-natal invasion, or the disease will run an atypical course *in utero* with or without apparent vestiges at birth. The entrance into the fetal structure is accomplished through the fetoplacental circulation. Bacterial action probably renders the placental villi less resistant. As a rule, the infectious diseases do not manifest their characteristic visceral lesions in the fetus, probably because of the passivity of these organs during antenatal existence. The germs, however, may often be detected.

33.—See abstract in The Journal of June 9, p. 1489.

34.—Ibid.

39. **The Physician and Surgeon in Abdominal Practice.**—Benedict argues for the importance of the physician and the presurgical diagnosis in surgical diseases of the abdomen. The surgeon should not pretend to possess double skill and act as diagnosing physician as well as the operator.

40. **Hay-fever.**—Hollopeter believes the important thing in hay-fever is to carefully study the nasopharynx. If no extensive lesions exist, he thoroughly sprays the pharynx with warm 2 per cent. Dobell's solution and follows this with a small applicator, armed with absorbent cotton dipped in a saturated solution of boric acid, with which he thoroughly touches all parts. He gives the following prescription as efficacious and having excellent keeping qualities:

℞. Adrenals (Armour's) desiccated...........ʒi
Acidi borici ....gr. xvi
Cinnamon water ....ʒiv
Camphor water (hot)......................℥i
Aquæ destil (hot) q. s. ad...............℥ii

M. Macerate for four hours, then filter.

The surgeon will find this extract a great aid in all minor operations, and to insure results, a pure suprarenal substance should be used. After the use of the spray and atomizer in the anterior nares, he uses an oily application for a protective covering, containing as its base liquid petroleum, with camphor, menthol, and an oil of palmetto in solution, and carefully applies it to the whole membrane previously treated. As a rule, he begins this treatment at least one week before the expected onset and continues it daily, sometimes twice daily, until ten days after the attack.

52. **Nature of Cancerous Processes.**—Park's paper discusses the nature of cancerous growth, with special reference to its infective and inoculative transmission and the malignant transformation of simple lesions like cicatrices, ulcerations and non-malignant ulcers. Cancerous cachexia is principally a complex product of numerous factors, including degenerative products, both from neoplastic cells and disturbed action of normal cells, the anemia from hemorrhage, secondary septic infections and renal lesions.

54. **Uterine Myomata.**—The indications for operation for uterine myomata are divided into three groups by Ill. In the first class are those in whom life may be endangered directly or indirectly by the growth, including bleeding myomata, septic and sphacelated myoma and the tumors producing extreme pressure, those growths which become strangulated by torsion or impaction, those accompanied with extensive and recurrent inflammatory diseases of the appendages, those occurring during pregnancy and in young women under 30 years, those associated with attacks of peritonitis, or inflammation of the tumor itself, cases of doubtful diagnosis, those of special location producing serious symptoms of hemorrhage, cases where there is a suspicion of malignancy, where there is excessive serous mucus or mucopurulent discharge, severe uterine contraction causing presentation of the tumor at the os. and those favoring a septic inflammation, and tumors occurring after the menopause which are suggestive of malignant disease, or where inversion of the uterus has been produced. The second group includes those cases where health is so seriously impaired that life becomes a burden, though it may not be in danger, and includes cases of enlarged size, excessive mobility, adherence of pedunculated tumor to the bowels, mesentery or bladder, mild inflammatory disease of the appendages, excessive menstrual pain and pain in general. Under the third class are included those in whom the mental condition suffers from the fact that they have a tumor, those sensitive, usually unmarried, women with large growths, those who "harp" on their condition, and those who can not separate in their minds a tumor from a cancer. Any of these are likely to demand an operation. The contraindications to operation are when the patient is unaware of the trouble, or has discovered it, but suffers neither mentally nor physically, when the symptoms are slight, in women who can nurse themselves, those near the menopause who can be relieved by clothing, abdominal supporters, food, etc., women suffering with other more serious diseases likely to be fatal, such as phthisis or Bright's disease, which is not connected with the growth. As regards the operation, he rather favors the abdominal route. but the operator should take his choice of the vaginal route when the tumor is freely movable and can be easily pushed into the cavity of the pelvis and the vagina is wide enough for easy and comfortable operation, and also when there is complete chronic inversion of the uterus. He is not partial to total extirpation of the uterus by the supravaginal method and believes rather in supravaginal amputation.

55. **Relation of Pregnancy to Nervous Diseases.**—According to Putnam, we must consider the relation of pregnancy to nervous disorder in two ways, i. e., the effects of pregnancy on the already existing disorder and pregnancy as its cause. It has never been found that pregnancy has any effect on epilepsy, for as as rule patients are neither better nor worse. No one should delude himself that marriage with an epileptic is safe or wise. Pregnancy has been observed as a cause of epilepsy several times. The chorea of pregnancy is, in his opinion, not so very serious a condition, or at least not the fatal disease which many writers would have us believe. The necessity for producing abortion in this case seldom arises. Diabetes may occur during pregnancy and at no other time; and it is noteworthy that in these cases coma has seldom developed. In twenty-two cases studied by Matthews Duncan, four were fatal, but they died in collapse, not in coma. There is no ground for holding that diabetes mellitus appears more frequently in pregnant than in non-gravid women. Tetany has been observed many times in Europe in connection with pregnancy, though it is less common in this country, and is more liable to occur in those who have had the disease before marriage. Nervous diarrhea has been observed in about 1 per cent. of several thousand cases in the Turin Maternity. The relation of exophthalmic goiter with pregnancy has been but indifferently studied. Dreschfield and Charcot have observed cases that improved markedly, if allowed to go full term; sometimes improvement has been observed and again it has appeared to make it worse. Further investigations of the effect of pregnancy on pre-existing exophthalmic goiter, and on pregnancy as a direct cause of the disease, are needed. Hysteria has been caused by pregnancy and is liable to be aggravated by it if existing before. There is, however, no tendency in the hysterical to premature labor. Myelitis has been observed in several cases as a result of septic infection. The insanity of pregnancy is well known, the insanity of childbirth is, according to Putnam, in many cases septic in its origin, and generally takes the maniacal form, in contrast with the disease when it occurs during pregnancy, which is usually melancholic, according to his experience.

56. **Prostatectomy.**—Thorndike advocates Alexander's operation as the best fitted for the relief of prostatic trouble. He believes that the entire prostate is thoroughly and entirely removed by enucleation; and that it is a comparatively bloodless operation. Its range of usefulness will be much widened when its value is fully recognized by surgeons.

63. **Impetigo Adenosa.**—The observation of ten cases of a peculiar type of skin trouble has led Aronstam to describe it under the above name. It is an acute, contagious, febrile affection characterized by an eruption of pustules, accompanied by enlargement of the lymphatic glands in their various situations. The disease is no doubt contagious, but bacteriologic data are wanting. It is usually ushered in with vomiting of a protracted type and a decided chill of short duration, followed by a fever, the temperature ranging from 101 to 104 F., the pulse ranging from 120 to 140 per minute, and the breath heavy and offensive. Small moist râles could be heard all over the anterior surface of the thorax, and pain was present in the joints, and especially in the posterior tibial muscles. The children were prostrated and apathetic. The trouble lasted from two to three days, after which pustules began to appear on the more exposed portions of the body, they were glistening and contained a yellow, translucent fluid, and were surrounded by a vivid scarlet-colored zone. They appeared simultaneously with the swelling of the lymphatic glands of the groin and neck, some of these even attaining the size of a small hen's egg, and being very painful and tender on pressure. After a day or two, the pustules increased in size and finally ruptured, after which the symptoms began to decline, and the appetite to return. The contents of the pustules dried up and changed into crusts of a yellowish hue, surrounded by a raised border of mahogany color, and this by a deep red area. After three or four days the crusts fell off, the color disappeared, the normal healthy integument returned, the tongue cleared up, and the patients were quite comfortable, but the glands remained more or less painful for a week or ten days, and in all the cases, there was a burning, itching, and smarting, the former being quite excessive, and these coincided with the lesions. Every case recovered completely, with no after-effects or complications, except alopecia in one case. Nothing seemed to affect the disease, although the treatment was symptomatic, calomel being given to relieve constipation, which was invariably present; and bismuth and lime-water for the vomiting. The ice-bag to the head relieved the cerebral symptoms, and iced lemonade was given freely. The itching and burning were relieved by an ointment of zinc dioxid, ichthyol, and menthol—the latter of 1 per cent. strength—aplied twice a day. The swollen glands were completely covered with gauze saturated with a lead and opium wash, which had no effect, but iodin seemed to do better. During convalescence, cod-liver oil with the hypophosphites and the syrup of ferrous iodid was prescribed, together with good feeding, plenty of fresh air and exercise.

68. **Chronic Deforming Polyarthritis.**—Walls reports a case of arthritis deformans in a child 5 years old, which has been improved by change of surroundings, more hygienic quarters and better food, and he has hopes of seeing complete recovery. He discusses the condition and says that the treatment mainly consists in supplying abundant fresh air, good food and in giving attention to the skin and nutrition. During the acute periods, salicylate of soda and antipyrin with soothing oils and ointments are of value. In the interval, general tonics such as cod-liver oil, iodid of iron, tincture of iodin, arsenic, massage and galvanization are likely to be useful.

81. **Venereal Hygiene of Future.**—Sholl's article is an imaginative one of the "Looking Backward" type, showing the condition of things in the ideal community of the future, in which marriage is regulated, criminals are unsexed and degenerates generally eliminated.

84. **Malaria and Mosquitoes.**—Moody claims that the question of the agency of mosquitoes in all cases of malaria is not yet settled. He believes that there are places where mosquitoes do not exist and malaria does, and that there is more than one method by which the germ of malaria may reach the blood. He also thinks it possible that it may be introduced during the mosquito season and lay dormant for months before producing its special effects. Another theory is that the different plasmodia have different modes of propagation and introduction. He says that the question is a very interesting one and one that calls for thorough study by the physicians of the South. He has seen cases of typical double tertian occurring in towns where no mosquitoes have been seen for months.

89. **Gasoline as a Surgical Detergent.**—From the action of this agent in cleansing wounds soiled with what railroad men call black-oil, Riordan was led to consider its efficiency as a surgical detergent. He finds that it has a decidedly antiseptic action when applied on cotton gauze, and that it does not irritate fresh wounds. It will be necessary to keep it from getting into the cavities, such as the eye and ear, where it is irritating, but if applied to surfaces where it can rapidly evaporate, it gives a cool, pleasant sensation. Microscopic appearances of the skin after being scrubbed with soap and water, and after being wiped off with gasoline, showed that the cleansing effect of the latter went much deeper and cleaned out the mouths of hair follicles, sebaceous glands and sweat ducts much more perfectly than did the soap and water.

71. **Ergot in Obstetric Practice.**—After noticing the opinions of various authorities, Hastings concludes that the use of ergot is always attended with more or less danger to the fetus *in utero*, and that it should be given twenty minutes before its action is required, and given to secure tonic contraction. He believes that it is valuable in preventing postpartum hemorrhage and in closing up the channels of septic absorption.

92. **Chloretone.**—Rudolf has experimented with chloretone on animals with special reference to its physiologic effect, and concludes that it would seem from Houghton and Aldrich's results, to be an ideal general anesthetic for physiologic work. It has for hours little or no effect on the pulse, respiration or blood-pressure, but eventually, if the dose is large enough, these become depressed and the animal dies, the heart stopping first. It is also more depressing on the bodily temperature than other drugs with which he is acquainted, excepting alcohol, and, therefore, should be used with great caution in medical practice. This is the more important as the drug is very slowly eliminated and has no known antidote, excepting perhaps external warmth.

96. **Communicable Diseases.**—Allen reviews the principal communicable diseases and their methods of dissemination, and suggests the instruction of the public in regard to the following points: That the dust from infected handkerchiefs, when the secretion has dried, often contains germs; and that they should, under no circumstances, be used after any secretion from the nose has been permitted to dry on them, and that after being used they should be placed in a paper bag, the top twisted shut, and there remain until they can be boiled in water; that contagion is liable to be spread by dust from floors or articles on which infected sputum or saliva has been ejected; by contact with the hands of persons who cough or spit into handkerchiefs, and then handle infected material; clothing often contains the germs of a communicable disease; books, pencils, chewing-gum, drinking-cups, etc., which are used in common, are often sources for the spread of contagious diseases; that while typhoid fever is ordinarily caused through the medium of drinking-water which has been contaminated with sewage or with leakings from privies, it is not improbable that it is sometimes spread by means of dust containing the germs of the disease.

97. **The Three Symptoms of Rickets.**—Berkeley calls attention to the haziness of the conception of rickets by many of the profession, and notices its most constant and striking symptoms. The first of these is the costal rosary or nodes, which are sometimes missed by the examiner because they are farther back from the median sternal line than in the adult, occasionally there being only an angle instead of a node. The typical rickety cranium is most noteworthy in the prominence of the parietal bones, which gives its characteristic box-like shape. The anterior fontanelle remains open late, often being greater at two or two and a half years than it should be at its greatest normal size. The sutures may be more or less separated and the bones thinned or softened. The latter condition—craniotabes—sometimes occurs with normal shaped heads. The shape and size of the liver and spleen should always be investigated, as the chronic intestinal indigestion of rickety infants furnishes toxic matter enough to cause swelling of these organs; and to this must be added the influence of the secondary anemia of the disorder. The enlargement is sometimes astonishing and causes many adventurous essays in diagnosis. Why one or the other shoud exceed in this respect is not clear, but the spleen is most apt to reach remarkable size.

100. **Brain Traumatisms.**—In the majority of injuries to the brain, the lesions are multiple and the general symptoms mask the local ones, while the general depression may be so prolonged that the latter may be observed too late to be of real value, and hence, the importance of localizing symptoms in injuries to the brain is not so great, acording to Williams, as has been supposed. He believes that simple surgical shock is the cause of many of the symptoms credited to concussion or depression, and that the real pathogenic conditions causing prolonged unconsciousness are often overlooked, attributing them simply to a depressed bone or hemorrhage. Too much stress is also laid on the presence of fracture; compound fracture is only of importance as affording a source of infection. He believes that operation on the brain, under proper asepsis, is as safe as an operation on the abdomen, and should be done as readily. More can be accomplished by early operative interference than has been, and drainage of the epidural region or even the pia-arachnoidal cavities will, in many cases, relieve intracranial pressure and restore nutrition.

103—See abstract in The Journal of May 5, p. 1131.

104. **Colorado Climate and Sleep.**—The effects of the climate of Colorado on sleep are described by Eskridge, who finds that in acclimated persons of temperate and regular habits sleep is continuous and refreshing. For those who lead iregular lives, keep late hours, indulge in alcohol and smoke a great deal at night, sleep will be more disturbed and less refreshing than at sea-level. During the summer months, it is always easier for the phlegmatic individual to sleep in Colorado than in lower altitudes. On the other hand, sleep is disturbed more easily by slight causes, though the need of it is somewhat less. In those who are over-worked mentally, sleep is broken and shorter, as the climate seems to disturb the nervous system in this respect more than in others. Those who are inherently nervous are likely to have trouble in getting sufficient sleep, but if they are careful not to take too much physical exercise the difficulty is relieved. The neurasthenic and the hysterical patient always have difficulty in getting enough sleep in Colorado, unless they take abundant rest. All stimulants seem to have a greater disturbing effect than at sea-level. Tubercular subjects sleep as well in Colorado as at lower levels, and better if they avoid over-exercise and excesses. Nervous people do not stand prolonged residence so well there as in lower altitudes. Sleep in unacclimated persons coming to Colorado may be increased or greatly les-

sened. For the majority of consumptive patients, sleep is worse on coming to Colorado, unless precaution is taken to diminish exercise. For the over-worked from the eastern sections, who do not have indigestion or brain changes, the climate of Colorado possesses the best means of overcoming insomnia and of building up the nervous system. For those who are troubled for sleep in that climate, a change once or twice a year is of advantage.

112. **Stone in the Bladder.**—Paschal says that each operation has its indications and must be chosen accordingly. Litholapaxy gives the lowest mortality, but is not suitable where the stones are very hard and large. In all cases where there is chronic cystitis and it is desirable to give the bladder rest, there is no better treatment than simply to open it. In unskilled hands litholapaxy is not as safe as the cutting operation. The perineal operation gives a smaller death-rate than the suprapubic, which is best suited for cases of very large stone and for old individuals with prostatic tumors or enlargements, but it is not suitable for children. A well-performed lateral operation leaves little to be desired and is suitable to all cases. The combined perineal and suprapubic operation may be done, when needed, with perfect safety. Perineal lithotrity is not a well-accepted operation, and has no particular advantages over other ones. The recurrence of stones after removal follows any operation, perhaps no more frequently in one than another. The cause that gives rise to their formation should be sought and treated.

118. **Tuberculosis in Children.**—Risinger believes that many cases of mucous catarrh are due to tubercle bacilli and that lesions of this nature lead to the development of the strumous gland. He adopts Still's views as to the route of infection being chiefly by the air-passages, the frequency of intestinal tuberculosis being due to the swallowing of sputum. He thinks that there is no disease which has a greater tendency to cure or to remain quiescent than tuberculosis, and that it generally attacks the bronchial lymph-nodes. He says that a large majority of children suffer during one period of their life from a benign and self-limited form of tuberculosis. For the great majority of these children, the prognosis is good, it is only the weaker that suffer from pulmonary tuberculosis and from autoinfection. Milk infection is, in his opinion, extremely rare.

119. **Appendicitis.**—Love discusses the subject of appendicitis and the medical and surgical methods of meeting it. He lays stress on the value of colonic irrigations, and says that if he was subject to the disease, with no imminent danger of perforation, he would have the intestinal canal thoroughly cleaned out, the pain controlled by hot and cold applications, ice-bags, etc., a snug, firm abdominal bandage over a sheet of oil-silk and a layer of cotton batting applied. The absolute withholding of food for a week or more is best in most cases. The ideal method is the surgical, but since it is not safe to trust to the average general surgeon or general practitioner for operation, medical treatment is important.

125. **Primary Renal Tuberculosis.**—Ramsay concludes that in renal tuberculosis some form of surgical treatment is always indicated, and that it may have a palliative or curative effect, according to the condition of the patient and extent of the condition. As a palliative operation, nephrotomy gives almost immediate relief of dangerous symptoms and does not preclude a latter nephrectomy. Resection of the diseased part of the kidney is always contraindicated in this condition. Nephrectomy or nephro-ureterectomy is always indicated where tuberculosis has not developed elsewhere or when there is no fatal disease of the other organs. Tuberculosis of the bladder or a small focus of tuberculosis in one lung is not considered a contraindication to nephrectomy and primary nephrectomy or nephro-ureterectomy has been followed in suitable cases by final cure in 56 per cent. With the present methods of examination and improved operative technique, the percentage of final cures should be materially increased.

127. **The Walcher Posture.**—Walcher's statement that the true conjugate gains from 1/3 to 2/3 inch has been denied, and after noticing what others have reported, Cutts says that in an examination of a female cadaver at the University of Minnesota, he found an increase of ⅛ inch in this position, while marked flexion reduced the true conjugate ¼ inch, making the total difference 3/8 of an inch. He thinks that this would be still further increased in the living pregnant state. The transverse and oblique diameters remain unchanged in the extended position, yet all lines radiating from the promontory to points of the superior strait are increased in somewhat the same proportion as the true conjugate. He believes that at least some cases of dystocia at the superior strait would be benefited by the Walcher posture.

128. **Plague.**—The plague is discussed by Flint, who mentions the origin and history of the present pandemic, and then describes what he has seen in Hongkong and in India. The Chinese, who are the principal victims in the former place, are about the filthiest people on the earth, though the conditions in Hongkong did not equal those in some Chinese towns. The spread of the disease seemed to be largely through rats, but still more by fleas. Flies and mosquitoes do not seem to infect human subjects much. The symptoms of the disease, as observed in Hongkong, are largely the same as described elsewhere, but the mortality is much greater than it was among the Indian populations, even of the lowest class. The plague measures in India were not so thorough as in Hongkong, and the bigotry and animosity of the natives gave more trouble than among the Chinese. The effects of the Haffkine's inoculations are noticed and statistics given of the experiments at Hubli, which seemed to show that it had a most beneficial effect.

129. **"Christian Science."**—The author describes "Christian Science," its doctrines, policy, etc., and discusses the cause of its growth and flourishing condition. He believes that it is a sort of religious mania, one of those delusions which are cunningly contrived to gain a strong and permanent foothold. There is always an element in a community that goes to extremes in adhering to its ideas. He does not think that there is much that can be done to combat this, except to correctly instruct the people, and see that the public is protected, that births, deaths and contagious diseases are reported and that small children are protected from "Christian Scientist" measures. They have so far usually escaped penalties by claiming that they do not give any drugs or other medical treatment.

131.—Ibid.

132.—Ibid.

145. **Vaccination—A Correction.**—In an abstract in The Journal, June 23, of an article by Dr. F. J. Runyon, in the *Memphis Medical Monthly*, the statement was made that he deemed that only about 25 per cent. of those vaccinated are immune. It should have said that he claimed only 25 per cent. of successful vaccinations with glycerinated lymph were efficient in immunizing.

Physician and Surgeon. June 21.

Pelvic Pain in Women Caused by Impacted Ureteral Calculi. Septimus Sunderland.—From his experience, some of which is here reported, Sunderland asserts his belief that a large number of women suffer from pelvic pain in varying severity by a stone in one or the other ureter and the pain is likely to be considered by the attendant as due to ovarian or uterine trouble, or regarded as of neuralgic, neurotic or hysterical origin. Occasionally, if the pain be situated on the right side, the appendix may be credited as the source of trouble. He advises that skiagraphs be taken of the kidney to discover if stones are present. In doubtful cases also one should have recourse to careful palpation of the abdominal parieties, inspection of the orifices of ureters with the cystoscope, examination of the urine and other methods for verifying or otherwise the presence of these complications in this situation.

British Medical Journal, June 23.

Degeneration of the Neurone. Frederick W. Mott.—The author first gives the history of the neurone, the objections to it by Apathy and Bethe, the various elements of the neurone and their physiology, and passes to the degenerations of this unit of the nervous system. After the historical introduction, in which he gives Dr. Waller's theory, he shows that while there is traumatic degeneration there are other forms, like disuse-atrophy as shown by Dickinson and others. Senile decay is also mentioned, and he passes to the physiologic facts in regard to the functions of this organ. Before going into the detailed account of his own observations, which will take up the most of three following lectures, he gives a few illustrations relating to the neurone theory as regards the transmission of impulses and certain physiologic problems connected with the variable resistances to transmission of the spread of excitation. The lecture may be considered as a preliminary one bearing on the general facts that are necessary to learn in regard to the anatomy and functions of the nerve units, and should be read in full.

The Lancet, June 23.

Some Notes on the Introduction and Spread of Plague. G. J. Blackmore.—The writer calls attention to the great extension of plague throughout the world and the possibility of its introduction even into Great Britain. Experience has shown that during the first year only a few cases occur, and those generally not of a serious character, and the disease apparently disappears. The following year it, however, is seen again about the same time, there are more cases and the disease is more serious, but can scarcely be called an epidemic, and once more it disappears, only to appear again the third year, when we can see the epidemic visitation. This is Calcutta's experience and has been repeated universally. We do not know how the plague is transmitted from one person to another. It seems improbable that it occurs through the air or by mere contact. It is probable that it occurs from inoculation, though much more probably by means of insects and fleas. We know little more about its passing from place to place, though the fact that rats suffer from the same disease is significant. The statement that there is no mystery about the plague and that it can be stamped out is liable to do harm by creating a false security. Blackmore says that plague is liable to appear in mild form and sporadic cases and not be recognized. This is the probable source of many unexplained outbreaks, and a special danger is that it may not only reappear in the same place, but that it may spread to different places. He advocates the strictest examination of all vessels from plague-infected ports, and that all ports where the disease has occurred should be still considered, for a time at least, infected. All persons who come from places where plague is present or suspected should consider themselves possible sources of infection and should not treat even an apparently slight indisposition lightly for at least ten days after leaving the vessel that has been in an infected port. The crusade against rats and bedbugs should be most thorough, and the disinfection of rags and dirty clothing should be carefully attended to. A sharp lookout should be kept for an increase in the mortality of rats and a search made for the plague bacilli in the bodies of those found dead. Preventive inoculation should be early resorted to.

A Plea for Early Operation in Cases of Undoubted Tubercle of the Lung. J. Foster Palmer.—The author advises operation in cases of tuberculosis and shows how such interference with lung tissue may be often productive of a cure. The chief dangers are collapse, surgical emphysema and hemorrhage. The introduction of bacteria from without can be prevented by modern antiseptic methods.

Comparative Germicidal Action of Some Disinfectants. Arthur H. Burgess.—The writer has experimented on mercury biniodid, mercury perchlorid, chlorinated lime, formal aldehyde, lysol, carbolic acid and a number of other preparations, and tabulates the results of his experiments. The germ experimented with was the bacillus coli, which has, for a non-sporing bacillus, a high power of resistance to germicides. His method is explained in detail and consisted in obtaining a pure culture, making sub-cultures upon the potato. The characteristic dark-brown growth was removed with a thick, sterilized peptone wire and mixed in a vessel with a little sterilized peptone bouillon to form a thick emulsion, into which silk threads were immersed. They were carefully sterilized previously, and after immersion in the emulsion for ten minutes were transferred with sterilized forceps to a Petri's capsule, in which they were partially dried in the dark, in a temperature of 24 C. for three hours. They were next transferred to the disinfecting solutions to be tested and, after remaining in these for the required time, were lifted out with a sterilized platinum hook, washed in sterilized water and placed in a separate tube of peptone bouillon. These tubes were incubated at 37 C. for ten days, being examined each twelve hours for forty-eight hours, and daily thereafter. If no growth occurred, the bouillon was perfectly clear at the end of that time; if it did occur, it began to show signs of turbidity within from twelve hours or less to seventy-two hours. The presence of growth was shown by microscopic examination, and by inoculation of gelatin plates. If no growth occurred at the end of ten days it was concluded that all bacilli had been killed with the disinfectant solution. In every case a control experiment was made precisely as above, except that sterilized disinfectant water replaced the disinfectant solution and in each instance growth was found to be present at the end of twelve hours According to the table given, mercury biniodid takes first rank as a disinfectant, following this is mercury perchlorid; chlorinated lime, formal aldehyde, lysol and carbolic acid follow at long distance below. The formal adehyde is prepared from the Schering formula and the preparation stated in the table referred to formal aldehyde and not to formalin.

Brazil Medico (Rio Janeiro), May 1, 8 and 15.

Sublimate-Serum and Vaccination in the Plague. C. Terni.—The Italian government commissioned Professor Terni, director of the Institute of Hygiene at Messina, to study the plague and yellow fever in South America, and especially to test Baccelli's endovenous injections of sublimate. He states that Haffkine's vaccination, as modified at Messina, is the best method of immunizing men and animals against the plague. By his modifications he produces a vaccin much more rapid and active in smaller amounts than is obtained by any other method. A man inoculated with 2 c.c. has a chill and slight temperature in four hours, but sleeps well and wakes sweating profusely, in normal condition, except for pain in tumefied glands, and is able to attend to his affairs within twenty-four hours. A serum of great curative value can be produced in animals hyperimmunized with virulent cultures. The "beef" and the monkey are best adapted for the purpose, all animals being rejected that are not naturally extremely resistant to the inoculations. This antiplague serum stimulates phagocytosis and, combined with .5 per cent. sublimate in endovenous injection, proved remarkably effective in the four cases of plague in which it was tried. The germs rapidly vanished from the blood and three patients promptly recovered. The fourth showed marked improvement and treatment was suspended, but the patient died and the deep glands were found gravely infected from a primary bubo in the axilla. In all treatment of the plague, radical extirpation of the foci and surroundings is imperative, and the prognosis depends upon the thoroughness with which this is done. Terni obtains his extremely virulent material by inoculating guinea-pigs or monkeys with the plague bacillus direct. He first injects 10 to 15 c.c. of glycerinated bouillon or of a simple aqueous solution of 1 per cent. sodium chlorid and 3 per cent. pure glycerin, following this with a droplet of plague bacillus. The animal dies in two or three days and the peritoneal cavity contains about 30 c.c. of an exudate which is an actual "cream" of plague bacilli. A single drop of this exudate will kill a guinea-pig or monkey in twenty-four hours. One unit by weight of bacterial protein—equivalent to a liter of glycerin beef-tea culture—is contained in about .5 c.c. of this exudate, which has to be diluted to a fifth to prevent coagulation. He uses 1 mg. of the dry exudate of 1 c.c. of an aqueous solution of .5 per cent. sodium chlorid and carbonate; the latter has a tendency to soften the envelope of the bacteria. He avoids injury to the elements of the vaccin by sterilizing it at the low temperature of 55 C., repeated at intervals during several days, and then adds 1 per cent. [illegible] ic aci[illegible] This vaccin is extremely rapid in its action [illegible] 1 to 2 c.c. are required, as mentioned [illegible] time, material and effort.

Yellow Fever. C. Terni.—Sanarelli's icteroid bacillus was found constantly at the autopsies on persons who died of yellow fever, but it was never found in patients with other diseases. The chief anatomo-pathologic lesions in yellow fever are always in the small intestine, and Terni considers the disease a gastrointestinal infection. The method of vaccination described above can be applied to yellow fever; .5 c.c. will prove amply effective, and without serious after-effects. The blood of animals susceptible to infection and vaccinated—guinea-pigs, rabbits and dogs—shows the agglutinating reaction and marked antitoxic power. Dogs and rabbits, after the reaction to the vaccination is past, readily bear doses of the virus ten times stronger than is required to kill the control animals and their serum possesses intense bactericidal action. These and other facts he has established, impel Terni to propose vaccination against yellow fever as a means of individual prophylaxis. The evidence is decidedly in favor of water as the medium of contagion; aerial infection and also flies and gnats as media must be excluded. In all his research the icteroid bacillus was found on only one fly. Lacerda's theory of the symbiosis of the icteroid with a mold should be thoroughly tested; at present it seems to conflict with the fact that molds secrete acids, while acids are known to have an unfavorable effect on the development of the bacillus. Serotherapy of both plague and yellow fever is still in its infancy, but promises much for the future.

Annales de Dermatologie (Paris), May.

Non-Parasitic Nature of Eczema. C. Kreibich.—In the course of extensive research on cutaneous suppurations, conducted at Kaposi's clinic, Kreibich found the staphylococcus or streptococcus in twenty-six out of forty-one cases of vesicular eczema. But it was impossible to induce acute eczema in other subjects by inoculating them with either the serous fluid or the microbes derived from it. The inflammatory papulous nodule and the rapidly drying vesicle which followed the inoculation in certain cases, were merely a non-specific reaction of the skin to any irritation, whether caused by a microbe, a mold or by the chemical or mechanical action of any substance. These lesions have a natural tendency to elimination of the irritating agent and hence to spontaneous recovery, but they are liable to invasion by pyogenic microbes sooner or later, transforming the vesicles into pustules. The negative results of these inoculations and the fact that the fresh lesions in acute eczema are sterile, while only the old contain pyogenic microbes, confirm the non-parasitic etiology of the affection.

Bulletin de l' Academie de Medecine (Paris), June 12.

Abdominal Testicular Ectopia. Lucas Championnière.—A frail, poorly-developed child of 11 years of age was operated on by the writer twelve years ago on account of true, bilateral cryptorchidia, or abdominal testicular ectopia, with bilateral inguinal hernia. The testes were sought, mobilized and transplanted in the region of the absent scrotum in a cavity dug out for each with the fingers. The vas deferens and testicular artery were the only support left for one, which was less developed than the other. Each testis was transplanted separately. The first result was the disappearance of the pains occasionally noted before, evidently caused by the attempts at hernia of the testes. The general health was completely transformed within a year. The child has developed into an exceptionally strong, well-built young man. The testes have worked up a little from their first position, the smaller to a point over the scar of the hernia, and it has recently been extirpated on account of pain during physical effort. There was no evidence of spermatogenesis in this extirpated testis, but the genital functions were otherwise regular, with frequent erections. As far as the writer could learn, this is the only operation on record for double abdominal ectopia of the testes. The remarkable transformation in the general health and normal development of the genital functions after transplantation of the ectopic testes are significant facts, applicable also to inguinal ectopia. He has operated in thirty-seven cases of this latter kind, six of which were bilateral. He always seeks to retain the testes, for even if they do not serve for spermatogenesis, they certainly aid in the normal development of the general physique and genital functions. The testes frequently descend spontaneously in very young subjects and consequently he does not advocate expectant treatment in these cases unless forced to operate by pain or defective development. When the testis fails to descend there are usually fibrous adhesions above which hold it, and consequently traction is useless until these have been severed. If the vas deferens is too short to allow transplantation, castration is the only resort.

Semaine Medicale (Paris), June 13.

Should We Treat Fever? R. Lepine.—The ancients considered fever salutary in disease, and this view has been maintained as a sort of dogma until this century, but many now combat the heat as the chief enemy in disease, proclaiming, with Liebermeister, that treating the hyperthemia is treating the fever. The conclusions of Lepine's article—which will be presented at the International Congress in August—are that although the hyperthermia usually is an indication of the gravity of a febrile disease, it is far from being the principal factor, and that the aim should be to treat the fever specifically. This can be accomplished in diphtheria, malaria and articular rheumatism, but in other diseases we are restricted to merely supervising the reaction of the organism, moderating it in certain cases with antipyretics, which are to some extent specific for certain pyrexias. In others we must stimulate the reaction with hydrotherapy or by the application of cold, and in others by sustaining the general system. It is the task of therapeutics to pursue the infinite complexity of the elements of disease and give the patient the benefit of all our resources as conditions arise to demand them. Quinin seems to have a semispecific action in la grippe, and also pyramidon—which Lepine much prefers to antipyrin, as better tolerated and requiring smaller amounts for the same dose—and similar drugs have an unmistakably favorable effect. In anemia, also, the fever should be treated; only harm can result from allowing the febrile consumption to continue, and quinin will usually arrest it. Tuberculosis is also another condition in which the fever must be combated, always bearing in mind—while of necessity using them—that antipyretics, even the most harmless, sometimes induce collapse in phthisical subjects. Alcohol is also serviceable in their case as an adjuvant. The treatment of typhoid fever which at present gives the best results is cold baths with the correctives indicated by the individual case. This treatment cools and stimulates the febrile reaction and also the nervous system. It is most effective in typhoid fever, cerebral rheumatism, and in certain cases of eruptive fevers. In pneumonia, hyperthermia, even extreme and for two days, is not necessarily injurious. This disease, with its extensive local lesion, can scarcely be called a pyrexia, and the benefit of digitalis must be ascribed to its influence on the heart rather than on the hyperthemia. It is possible that the high temperature may have an unfavorable influence on the pneumococcus, or may favor the defensive reaction, or both combined.

Dermatologische Zeitschrift (Berlin), June.

Syphilis of the Stomach. Max Einhorn.—Syphilitic ulcer of the stomach has been observed a number of times, but syphilitic tumor of this organ is rarely discovered on autopsy, and has seldom, if ever, been diagnosed during life. Einhorn reports two cases of each of these lesions—the tumors simulating malignant neoplasms—cured by specific treatment. He also describes two cases of stenosis of the pylorus in syphilitic patients, with the familiar symptoms of ischochymia, etc., rebellious to internal treatment and apparently demanding surgical intervention. A tentative course of potassium iodid resulted in prompt and permanent recovery.

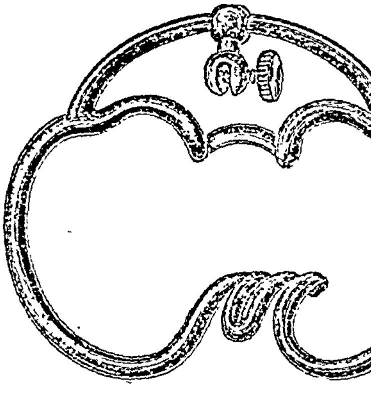
Syphilis of the Kidneys. J. J. Karvonen.—This comprehensive study of renal syphilis in all its manifestations has been continued from Volume v, and the end is not yet. All cases on record are critically analyzed and personal observations described in detail. Karvonen emphasizes, however, the fact that "ordinary nephritis" may occur at any stage of syphilis.

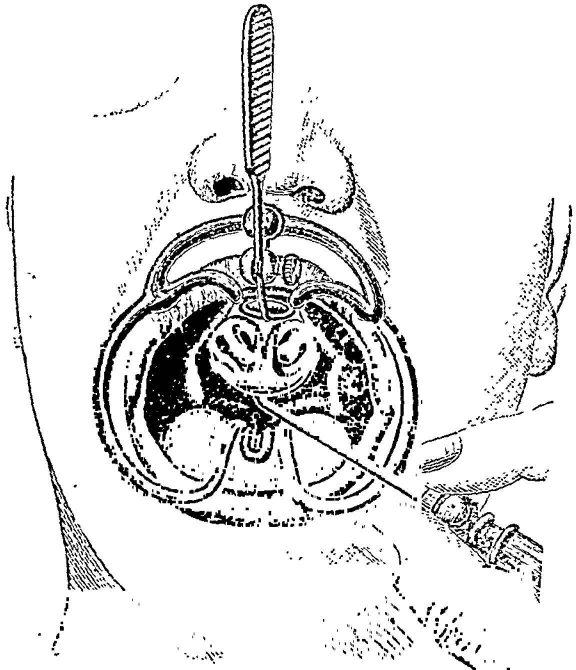
Deutsche Medicinische Wochenschrift (Berlin), June.

Fourth Report from Malarial Expedition. R. Koch.—This communication is dated April 28, and confirms the remarkably favorable results of the prophylactic and therapeutic measures instituted by Koch at Stephansort, described in former reports. The dreaded rainy season has come, with no new cases and only a few recurrences. Fresh infection is sure to occur when susceptible new-comers arrive, but this infection is easily kept under control. The important fact has been established that workmen imported from malarial regions are immune to infection, while those from malaria-free districts are liable to suffer severely. Another important fact is the necessity of investigating the blood of latent, mild cases of malarial infection, which have very slight clinical manifestations, but may be dangerous sources of infection. Koch reiterates his assertions that it is possible to eradicate malarial infection entirely or approximately in any malarial region, by the measures proposed.

Wiener Klinische Rundschau, June 20 and 17.

Automatic Tongue Depressor for Posterior Rhinoscopy. M. Paunz.—Strong wire is bent to form a continuous tongue depressor and circle to hold the mouth open; a slight bend in the wire at the top of the circle fits under the middle of the upper lip. An additional piece of wire, springing from the circle just below the nose, forms an arch with a slit ball and thumb-screw to hold the hook for the soft palate. This hook has a thin, flexible neck, and can be bent up toward the nose. The entire field is thus automatically exposed to view, broadly opened, with no hands nor instruments in the way.





Acute Occlusion Caused by Ovarian Cysts. S. G. Schalita.—In the case reported, an ovarian cyst had suddenly increased in size and caused acute occlusion with superficial pressure—necrosis of the ascending colon. In a second, similar case the intestine was found empty and dark-colored. The stem was twisted in each and the sudden occlusion was probably due to a hemorrhage into the cyst, induced by the torsion. The size and weight of the cyst had been much increased by this hemorrhage, with consequent compression and occlusion of the intestine on which it rested.

Muenchener Medicinische Wochenschrift, June 10.

Causes of Primary Iritis. v. Michel.—General examination of 84 cases of primary iritis at Würzburg disclosed chronic nephritis in 34.5 per cent.; tuberculosis in 36.8; affections of the circulatory apparatus in 15.4; syphilis in 5.9; and various other affections in 7.1. The large proportion of chronic nephritis emphasizes the necessity of general examination and appropriate treatment in all cases of "primary iritis" and also of parenchymatous keratitis, which probably has a similar etiology.

Operative Treatment of Inversion of the Uterus. W. Thorn.—Total inversion three months after childbirth in a very anemic patient had resisted all treatment and attempts at reduction, hemorrhage occurring at every intervention. Thorn opened the anterior cul-de-sac, incised the anterior wall of the uterus, and was then able to reduce the inversion after breaking up the adhesions. The walls of the uterus were then sutured together, commencing at the fundus, and the organ was supported by a broad stitch taken through the anterior wall, the peritoneum of the cul-de-sac and the vagina. The bleeding was slight and the patient rapidly recovered, leaving her bed the ninth day, and the clinic six days later.

Idiopathic Osteopsathyrosis. L. Lange.—The photograph of a six-year-old, intelligent child is given, who was healthy until his twenty-second month, when a slight fall caused him to break one of his long bones, and since then he has sustained twenty-two fractures of this kind. There are no symptoms of rachitis except this fragility of the bones, and consolidation follows with remarkable rapidity.

Wiener Klinische Wochenschrift, May 31 June 7 and 14.

Agglutinating Power of Human Serum. J. Donath.—Landsteiner has recently called attention to the fact that human blood-serum has an agglutinating effect on the blood corpuscles of animals and also of other human beings, most pronounced when the serum is derived from very sick subjects. Donath has been studying the serum of anemic persons from this point of view, testing it on normal blood from himself and others. The agglutinating power in serum from chlorotic patients was strong in 18 cases, weak in 3, and absent in 7. It was extremely pronounced in one case of leukemia and absent in one of pernicious anemia. One serum agglutinated the corpuscles in his blood very strongly, while it had no effect on the blood of other normal persons; the amount of agglutination varied with the individual specimen of blood. The intensity of the agglutinating power is not proportionate to the severity of the anemia; it depends probably on more complicated factors.

Dislocation of Goiter. J. Preindlsberger.—When goiter recurs and extirpation is impossible for any reason, or in case of bilateral compression of the air-passages, Wölfler "dislocates" the goiter, i. e., he removes it from the spot where it is causing functional disturbances and slips it along under the skin and muscles to another point, usually higher, where it can no longer press on the air-passages or esophagus. The writer describes a successful operation of this nature on a parenchymatous struma in a girl of 14, which had suddenly assumed a rapid growth and threatened suffocation. The right half was extirpated and the other moved to a new position in front of the trachea, after ligating the superior thyroid artery. The struma was still supplied by the inferior thyroid artery sufficiently to prevent necrosis, but the ligature of the superior thyroid reduced the supply of blood, causing the struma to diminish gradually in size, as hoped and anticipated.

Agglutination with Blood of Mother and Fetus. J. Halban.—Further research in the same line as Landsteiner's, mentioned above, is reported by Halban. It establishes the possibility of a reciprocal immunizing process between the organisms of mother and fetus. There is frequently a marked difference between the maternal and fetal sera in respect to their power to agglutinate the red corpuscles in human blood and dissolve them. This power also depends to a certain extent upon the blood to be agglutinated—some blood is more susceptible than others. In cases in which the maternal—but not the fetal—serum possessed the agglutinating power, the former agglutinated the corpuscles in the fetal blood the same as in extraneous blood, and vice versa. The hemolytic power of the sera paralleled the agglutinating power, and the latter seemed to be about the same for bacteria, especially the cholera vibrios, as for the red corpuscles. As the agglutinins are probably albuminoid substances, and as the fetus takes albuminoid substances from the maternal organism for its nourishment, the fact of the absence of agglutinins in the fetal serum, when conspicuously present in the maternal, indicates a remarkable elective power of absorption on the part of the epithelium of the chorion. On the other hand, when the agglutinins abound in the fetal while absent from the maternal serum, they must be congenital, i. e., occur independently of the mother. We must therefore distinguish between congenital and acquired agglutinins and lysins, and between heteroagglutinins and isoagglutinins as well as lysins (see The Journal, June 30, Ehrlich on "Hemolysins," p. 1685). Halban proposes the term "idioisoagglutinins" for the congenital isoagglutinins found in the new-born infant. The appearance of idioagglutinins in the maternal or fetal serum may possibly be the manifestation of a reciprocal immunizing process occuring between the two organisms. Blood-cells are being constantly destroyed in the circulation and an exchange of organic fluids is constantly occurring in the placenta. These afford the conditions for immunization, and it is possible that the two organisms may thus influence each other, with the result of immunization. Assuming this to be the fact, the idioisoagglutinins and lysins must be regarded as the products of a reciprocal immunization between mother and fetus during gestation. The fact that the agglutinins are found more frequently in the maternal than in the fetal blood is explained by our knowledge that the fetus reacts less energetically to tuberculin, for instance; a new-born infant will bear doses in subcutaneous injection which would induce high fever in adults. When the idioagglutinins are found in adults it is posisble that they have persisted from the embryonal life. The most plausible explanation of the whole phenomenon of agglutination is that the agglutinating and hemolytic power of normal serum is a congenital property of certain substances which occur normally in the blood, possibly the globulin, or of a substance originating in a kind of self-immunization from the constant destruction of red corpuscles.

Gazzetta degli Ospedale (Milan), June 10.

New Characteristics of Organic Mitral Lesions. G. Bassi.—An anatomic fact hitherto undescribed is the greater length of the anterior valve-flap in mitral stenosis, as compared with the normal. The flap was longest in cases which presented marked symptoms of mitral stenosis during life without the characteristic valvular constriction being found at the autopsy. Bassi therefore states that unusual length of the anterior segment—generally associated with increased thickness of the flap and also of the chordæ tendineæ—is an indication of a true organic lesion of the mitral valve, affirming the existence of a mitral defect during life, probably with symptoms of stenosis. The other characteristic to which he calls attention is that of a clinical order, and consists in the doubling of the second, or pulmonary, sound observed in connection with a special modification of the radial pulse. Combining auscultation of the heart with sphygmographic tracings, the duplication of the sound corresponds to a brief intermittency, a slight lengthening of the descending branch of the pulse, which signifies a prolongation of the ventricular systole.

Nordiskt Medicinskt Arkiv (Stockholm), May 16.

Primary Sarcoma of the Pleura. Israel-Rosenthal.—Two cases of primary sarcoma of the pleura came under Rosenthal's observation in 1898. One was a healthy young coachman, who had been kicked in the thorax by a horse. Fever followed, the symptoms simulating a large pleuritic effusion with dyspnea and expectoration. Punctures were negative or brought out a small amount of a chocolate-colored fluid. After death from asphyxia a very large, isolated, round-celled sarcoma was found, which compressed the intact lung and forced it downward. All the other organs were sound. The acute and febrile course of the affection, with death in five or six weeks, is exceptional, if not unknown. The connection with the trauma was unmistakable. Loewenthal noted a similar coincidence in 800 cases of malignant tumors collected by him, including 316 cases of sarcoma, and Ziegler in 35 out of 171 sarcomata. In the second case the first symptom was *intermittent pain radiating from the left* hypochondriac toward the renal region and the iliac fossa of the same side; there were no gastric symptoms, no indications of pulmonary trouble except the pain, and no fever, but progressive emaciation. The pain and emaciation continued for fifteen months; the stethoscope indicated a moderate pleuritic effusion. A small, hard, tumefied intercostal lymphatic gland was noted below the nipple, but no cough, nor marked dyspnea. The diagnosis was primary cancer of the colon with secondary pleuritic effusion. The autopsy showed a primary, round-celled sarcoma, as large as the head of an adult, on the left pleura. The colon was exceptionally long and twisted. Stethoscopic signs of tumors in the thorax are not absolutely reliable, neither is the retraction of the thorax wall nor the sensation of increased resistance to the exploring needle; these signs are also encountered in chronic, non-cancerous pleurisy. On the other hand, diffuse dilatation of the thoracic wall and obliteration of the intercostal spaces are not certain indications of effusion, as they were noted with a solid tumor in the first observation. Bronchial respiration was also noted over the tumor in one case. The results of exploratory puncture were misleading in both cases.

Relations Between Basedow's Disease and Myxedema. C. Ulrich.—Study of forty-three cases of struma has convinced Ulrich that there is a close pathologic kinship between Basedow's disease and myxedema, the symptomatic divergences merely indicating differences in degree.

Miscellany.

NEW PATENTS.

Patents of interest to physicians, etc., June 19 to 26.

651,962.	Apparatus for treating respiratory diseases. Demetrius Boghean, Vienna, Austria-Hungary.
651,921.	Trephine. Allen De Vilbiss, Toledo, Ohio.
652,119.	Making sulfuric anhydrid. Rudolph Knietsch, Ludwigshafen, Germany.
652,217.	Electric belt. Michael A. McLaughlin, Los Angeles, Cal.
651,951.	Preparing remedial serum. Franz Nieman, Basle, Switzerland,
651,978.	Electric belt. Wm. C. Sedwick, Des Moines, Iowa.
652,202.	Artificial ear-drum. Laura H. Vickers, Philadelphia, Pa.
651,942.	Obtaining pyrobetulin. James Wheeler, Ilfracombe, England.
652,345.	Disinfectant. Francois C. Cartier, Paris, France.
652,319.	Time medicine-cabinet. Frederick A. Linger and J. A. Carlisle, Washington, D. C.
652,286.	Clinical thermometer. John F. Myers, Sodus, New York.
652,446.	Electromedical bath. Johann J. Stanger, Ulm, Germany.
652,525.	Artery forceps. Frederick A. Stohlmann and L. G. Pfarre, New York City.

CHANGE OF ADDRESS.

Dr. E. S. Albee, from Chicago to Oshkosh, Wis.

Dr. F. X. Adams, from 114 Grant St. to 1100 S. Main St., Akron, Ohio.

Dr. S. S. Adams, from Washington, D. C., to West Springfield, N. H.

Dr. L. E. Andrews, from 356 S. Hermitage Ave., Chicago, to North Manchester, Ind.

Dr. J. Q. Allen, from Montrose to Telluride, Colo.

Dr. F. L. Anton, from 737 Buena Vista, to Old Sta K, Los Angeles, Cal.

Dr. N. M. Black, from 128 Wisconsin St. to 1807 Grand Ave., Milwaukee, Wis.

Dr. W. E. Bewley, from Warrensburg to Morristown, Tenn.

Dr. M. W. Bland, from 239 Ogden Ave., Chicago, to Galion, O.

Dr. L. P. H. Bahrenburg, from Brooklyn, N. Y., to Pemberville, O.

Dr. J. M. Brigham, from 607 E. Ann St., Ann Arbor, to Howell, Mich.

Dr. W. A. Burleigh, from Morrow to Fordoche, La.

Dr. W. Bertrand, from Cloutierville to Rosa, La.

Dr. H. Beyer, from 291 S. Lincoln St., Chicago, to Orange City, Iowa.

Dr. A. H. Benson, from 667 W. Adams St., Chicago, to Lake Park, Iowa.

Dr. L. L. Beehler, from Chicago to Manchester, Iowa.

Dr. L. F. Bucher, from Rush Med. Col., Chicago, to Box 70, Walnut, Ill.

Dr. S. Brownstein, from St. Louis, Mo., to 16 Johnson St., Chicago.

Dr. E. W. Carpenter, from Hyman to Blossom, S. C.

Dr. A. L. Cowden, from Olathe to Burlington, Kansas.

Dr. L. Dawson, from Rannir Club to Bailey Bldg., Seattle, Wash.

Dr. M. D. Delaney, from 911 Duke St. to 913 Prince St., Alexandria, Va.

Dr. G. L. Dines, from Libertyville to Mine La Motte, Mo.

Dr. B. B. Eads, from 530 Grand Ave. to 683 Washington Boul., Chicago.

Dr. A. T. Finch, from Blacksburg to Clarksville, Va.

Dr. W. H. Fall, from 534 7th St. to 422 W. 7th St., Cincinnati, Ohio.

Dr. J. A. Hill, from Groveton to Lufkin, Tex.

Dr. S. P. Hart, from Chicago to Auburn, Ill.

Dr. H. M. Hall, from Augusta to Cedartown, Ga.

Dr. C. E. Ide, from 528 Washington Boul., Chicago to Newport, N. H.

Dr. E. G. Little, from 361 E. Couch St. to 53 E. 11th St., Portland, Ore.

Dr. H. L. Lynah, from Charleston, S. C., to Johns Hopkins Hospital, Baltimore, Md.

Dr. J. W. Lea, from Cuero, Tex., to Jackson, La.

Dr. J. M. Mitchell, from Pontiac, Ill., to Milwaukee Hospital, Milwaukee, Wis.

Dr. J. McFarland, from 421 W. Price St. to 442 W. Stafford St., Germantown, Pa.

Dr. W. C. Mabry, from Cleveland to Stillwater, Ohio.

Dr. W. O. Neal, from Charlesville to Asbury, Va.

Dr. O. A. Newhouse, from Chicago to Battleground, Ind.

Dr. E. S. Pettyjohn, from Chicago to 6 Rue Halevy, Place de L'Opera, Paris, France.

Dr. B. G. Pinkerton, from Beyrout, Syria, to City Hospital, St. Louis, Mo.

Dr. Delos L. Parker, from 397 to 559 Jefferson Ave., Detroit, Mich.

Dr. A. C. Page, from Chicago to Des Moines, Iowa.

Dr. W. J. Pinkerton, from Chicago to Ludlow, Ill.

Dr. George Rubin, from 7 Rue Scribe Robert to 11 Rue Scribe, Paris, France.

Dr. R. R. Reynolds, from Nilson and 6th Sts. to 219 Superior St., Cleveland, Ohio.

Dr. B. Reed, from Philadelphia, Pa., to Hammonton, N. J.

Dr. W. D. Ruhl, from 434 to 454 Calhoun St., Ft. Wayne, Ind.

Dr. E. S. Riggs, from Washington, Pa., to Hamills Point, Lake Joseph, Muskoka, Canada.

Dr. W. H. St. Clair, from Charlottesville to Bluestone, Va.

Dr. P. B. Schofield, from Newark, Mo., to Luling, Texas.

Dr. W. Shafer, from Chicago to Moracco, Ind.

Dr. E. J. Senn, from 25 Astor St., to 100 State St., Chicago.

Dr. I. Sewell, from Cedar Bluff, Ala., to Cave Spring, Ga.

Dr. S. J. Townsend, from Las Vegas, N. Mex., to Cherry Creek, Nevada.

Dr. W. H. Walker, from Chicago to Utica, Neb.

Dr. L. P. Walbridge, from 602 U. T. Bldg. to 5001 Vernon Ave., St. Louis, Mo.

Dr. F. L. Wilcox, from Chicago to Albert Lea, Minn.

Dr. R. Williams, from Chicago to Carthage, Ill.

Dr. G. Wood, from 348 E. 55th St. to 143 E. 35th St., Chicago.

Queries and Minor Notes.

LAWS REGULATING PRACTICE.

St. Louis, June 16, 1900.

To the Editor.—Kindly inform me whether a person holding certificates for three courses in a four-year school and a diploma (covering another year) from a school now graduating M.D.s after three courses, can practice in a state where four courses are required, or rather, would the receiving of a diploma from the three-year school bar him out, although he had taken four courses altogether?

W. F. S.

Answer:—Yes. A diploma from a three-year school is the same whether the holder has taken three or more courses and would not be recognized in those states which demand a four-years course.

Chicago, Ill., June 23, 1900.

To the Editor.—Regarding those state examinations, how is it for old practitioners who graduated under the three-year course? If a state requires a four-years course, is no allowance made for those who received diplomas before that law was passed?

D. C. B.

Answer:—No state can make *ex post facto* laws and so far as the exclusion falls under that head it would be invalid. A more definite answer can not be given without specifically referring to the different state laws.

DR. APOSTOLI.

Lafayette, Ind., June 24, 1900.

To the Editor.—Will you kindly inform me of the address of Dr. Apostoli, of Paris? I have tried several places but have been unable to obtain his correct address, and thought possibly you could enlighten me.

Very truly yours, E. C. D.

Answer:—The death of Dr. Apostoli was noticed in The Journal of May 26.

The Public Service.

ARMY CHANGES.

Movements of army medical officers under orders from the Adjutant-General's Office, Washington, D. C., June 22 to 28, 1900, inclusive.

Charles Anderson, acting asst-surgeon, from Santa Barbara, Cal., to duty at Fort Brown, Texas.

Lewis Balch, major and surgeon, Vols., previous orders of June 15, 1900, honorably discharging him from the service, revoked.

Christopher C. Collins, lieutenant and asst.-surgeon U. S. A., member of an examining board at San Francisco, Cal.

George H. Crabtree, acting asst-surgeon, from Chicago, to duty in the Department of California.

William D. Crosby, major and surgeon Vols. (captain and asst.-surgeon U. S. A.) honorably discharged from the volunteer service, to take effect June 30, 1900.

John R. Devereaux, acting asst.-surgeon, from Washington, D. C., to duty at Washington Barracks, D. C.

Robert J. Gibson, major and surgeon, U. S. A., relieved from membership on examining board at San Francisco, Cal.

Philip F. Harvey, major and surgeon, U. S. A., leave of absence extended; relieved from membership on examining board at San Francisco, Cal.

Augusta A. Nouel, acting asst.-surgeon, from New York City to Havana, Cuba, for assignment in the Division of Cuba.

Benjamin F. Pope, lieutenant-colonel, deputy surgeon-general, U. S. A., member of an examining board at San Francisco, Cal.

BOARD CONVENED.

On June 27, 1900, by direction of the acting secretary of war, a board of medical officers to consist of Major John Van R. Hoff, surgeon, U. S. A.; Major Peter R. Egan, surgeon, U. S. A.: Capt. George M. Wells, asst.-surgeon, U. S. A.; Lieut. Frederick F. Russell, asst.-surgeon, U. S. A., is constituted to meet at headquarters, Department of Porto Rico, San Juan, P. R., for the examination of candidates for admission into the medical corps of the army. The board will be governed in its proceedings by such instructions as may be communicated to it by the surgeon-general of the army.

NAVY CHANGES.

Changes in the medical corps of the U. S. Navy for the week ending June 30, 1900.

Asst.-Surgeon G. N. Fiske, ordered to the Boston navy yard.

Surgeon W. H. Rush, when discharged from treatment at the naval hospital, Mare Island, Cal., ordered to Washington, D. C., July 10, for examination for retirement, and then home to wait orders.

Asst.-Surgeon O. M. Eakins, detached from the *Buffalo* and ordered to the *Scindia.*

Surgeon C. F. Stokes, promoted to surgeon from May 31, 1900.

MARINE-HOSPITAL CHANGES.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the U. S. Marine-Hospital Service for the seven days ending June 26, 1900.

Surgeon H. W. Austin, granted leave of absence for one month from Aug. 2, 1900.

Surgeon G. M. Magruder, granted leave of absence for 10 days.

P. A. Surgeon A. C. Smith, granted leave of absence for 7 days.

P. A. Surgeon J. H. Oakley, granted leave of absence for 15 days.

P. A. Surgeon E. K. Sprague, granted leave of absence for 10 days.

P. A. Surgeon H. W. Wickes, granted leave of absence for 15 days.

Asst.-Surgeon S. B. Grubbs, granted leave of absence for one month from August 20.

Asst.-Surgeon J. F. Anderson, granted leave of absence for 10 days.

Asst.-Surgeon W. C. Billings, granted leave of absence for 18 days from June 28.

Asst.-Surgeon R. L. Wilson, relieved from special temporary duty at San Francisco quarantine and directed to report to medical officer in command at San Francisco for duty and assignment to quarters.

Asst.-Surgeon B. H. Earle, relieved from special temporary duty at San Francisco quarantine and directed to report to medical officer in command at San Francisco for duty and assignment to quarters.

Asst.-Surgeon J. D. Long, upon being relieved from duty at New York City (Stapleton) to proceed to Washington, D. C., and report to director of hygienic laboratory for duty.

Asst.-Surgeon Edward Francis, to proceed to New York City, (Stapleton) and report to medical officer in command for duty and assignment to quarters.

Asst.-Surgeon L. P. H. Bahrenburg, to proceed to New York City, and report to Surgeon L. L. Williams, immigration depot, for duty.

Asst.-Surgeon J. T. Burkhalter, to proceed to New York City (Stapleton) and report to medical officer in [illegible] for duty and assignment to quarters.

Asst.-Surgeon John S. Boggess, to [illegible] and report to medical officer in command [illegible] to quarters.

Asst.-Surgeon G W. McCoy, to [illegible] report to medical officer in command for duty and assignment to quarters.

Asst.-Surgeon C. C. Pierce, to proceed to Mobile, Ala., and report to medical officer in command for duty and assignment to quarters.

Asst.-Surgeon B. S. Warren, to report at Washington, D. C., for temporary duty.

Acting Asst.-Surgeon J. A. Rowles, granted leave of absence for 10 days from June 12.

Acting Asst.-Surgeon H. C. Sibree, granted leave of absence for 7 days.

Hospital Steward A. M. Roehrig, upon being relieved from special temporary duty at San Francisco quarantine, to rejoin station at San Francisco, Cal.

Hospital Steward F. R. Hanrath, relieved from duty at New York City (Stapleton) and upon expiration of sick leave of absence, to proceed to Cleveland, Ohio, and report to medical officer in command for duty and assignment to quarters.

Hospital Steward F. L. Gibson, relieved from duty at Washington, D. C., and directed to proceed to Honolulu, Hawaii, and report to Surgeon D. A. Carmichael for duty and assignment to quarters.

APPOINTMENTS.

Edward Francis, of Ohio, Louis P. H. Bahrenburg, of Ohio, John T. Burkhalter, of Georgia, John S. Boggess, of Ohio, George W. McCoy, of Tennessee, Claude C. Pierce, of Tennessee, and Benjamin S. Warren, of Alabama, commissioned as assistant-surgeons June 22, 1900.

Walter R. Hicks, of Michigan, appointed acting assistant-surgeon for duty at Menominee, Mich.

HEALTH REPORTS.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, U. S. Marine-Hospital Service, *during the week ended June 29, 1900.*

SMALLPOX—UNITED STATES

District of Columbia: Washington, June 16-23, 14 cases.

Illinois: Chicago, June 16-23, 7 cases.

Indiana: Indianapolis, June 15-22, 2 cases.

Kansas: Wichita, June 16-23, 3 cases.

Kentucky: Covington, June 16-23, 12 cases, 1 death.

Louisiana: New Orleans, June 16-23, 16 cases, 7 deaths; Shreveport, June 16-23, 3 cases.

Massachusetts: Fall River, June 16-23, 5 cases; Lowell, June 16-23, 1 case.

Michigan: Grand Rapids, June 16-23, 1 case.

New Hampshire: Manchester, June 16-23, 3 cases.

New Jersey: Jersey City, June 17-24, 1 case; Newark, June 8-23, 10 cases.

New York: New York, June 15-23, 4 cases.

Ohio: Cleveland, June 16-23, 12 cases.

Pennsylvania: Pittsburg, June 16-23, 1 case.

Tennessee: Nashville, June 16-23, 5 cases.

Washington: Tacoma, June 8-16, 1 case.

West Virginia: Charlestown, June 19, 14 cases; Wheeling, June 22, 1 case.

SMALLPOX—FOREIGN.

Austria: Prague, June 2-9, 8 cases.

Belgium: Antwerp, May 26 to June 2, 1 case.

Brazil: Rio de Janeiro, May 11-18, 7 cases, 5 deaths.

Canada: Province of Quebec, Bonaventure Co., May 21-28, 1 case.

China: Hongkong, May 5-19, 1 case.

England: Liverpool, June 2-9, 4 cases; London, June 2-9, 11 cases; Southampton, June 2-16, 2 cases.

France: Lyons, May 19-26, 3 deaths; Paris, June 2-9, 3 deaths.

Gibraltar: June 3-10, 1 case.

Greece: Athens, June 2-9, 4 cases, 2 deaths.

India: Bombay, May 16-29, 29 deaths; Calcutta, April 21-28, 41 deaths; Kurrachee, May 13-27, 61 cases, 48 deaths; Madras, May 5-25, 1 *death.*

Mexico: Chihuahua, May 26 to June 9, 4 deaths; Vera Cruz, June 8-16, 9 deaths.

Porto Rico: Ponce, June 4-11, 2 cases.

Russia: Moscow, May 25 to June 2, 13 cases, 3 deaths; Odessa, June 2-9, 6 cases, 1 death; St. Petersburg, May 26 to June 2, 47 cases, 8 deaths; Warsaw, May 19 to June 2, 6 deaths.

Scotland: Glasgow, June 15, 1 death.

Spain: Corunna, June 2-9, 1 death.

Straits Settlements: Singapore, May 10-17, 3 deaths.

YELLOW FEVER.

Colombia: Barranquilla, June 2-9, 4 cases, 3 deaths; Panama, June 11-18, 3 cases.

Cuba: Havana, June 6-17, 6 *cases*, 2 *deaths*; Santa Clara, May 16 to June 21, 26 cases, 8 deaths; Trinidad, June 19, 1 case.

Mexico: Vera Cruz, June 8-16, 15 deaths.

CHOLERA.

India: Bombay, May 17-29, 110 deaths; Calcutta, April 21-28, 92 deaths.

PLAGUE.

Arabia: Aden, May 12 to June 2, 170 cases, 100 deaths.

China: Amoy, June 23, reported; Hongkong, May 5-19, 155 cases, 142 deaths.

India: Bombay, May 17-29, 410 deaths; Calcutta, April 21-25, 343 deaths; Kurrachee, May 13-27, 154 cases, 115 deaths.

Japan: Osaka, May 25 to June 2, 4 cases; Shidzuoka Ken, May 25 to June 2, 5 cases.

Turkey: Smyrna, May 29, 1 case.

THE JOURNAL OF THE
AMERICAN MEDICAL ASSOCIATION

61 Market Street : : Chicago, Ill.

Cable Address: "Medic, Chicago"

Subscription price: Five dollars per annum in advance

Postage in the United States and Canada, Mexico, Hawaii, Guam, Porto Rico, and the Philippines, *free; foreign postage*, $2.50. Subscriptions may commence at any time. Volumes begin with the first issue of January and of July.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

The qualifications for membership require that the applicant be a member, in good standing, of a state or local medical society entitled to send delegates to the annual meeting of the American Medical Association. A list of these societies will be sent on request. Applications must be accompanied with a certificate showing that the applicant is a member *of a recognized society*, and should be sent with the annual dues—five dollars—to the treasurer, Dr. Henry P. Newman, 100 Washington Street, Chicago. Members receive The Journal free. Subscribers to The Journal may become members of the Association without additional expense if *they are members of medical societies* recognized by the Association. Those desiring to have their names transferred from the subscription to the membership lists should send certificates as above, with a receipt for their subscription to The Journal, covering the current fiscal year.

FISCAL YEAR.

The fiscal year of the American Medical Association is from January 1 to December 31; and the annual dues paid by a new member cover only the fiscal year, no matter at what time of year the membership is obtained. Those who pay their dues and join the Association at the annual meeting in June, for instance, pay only for the fiscal year which ends with the December following, and the annual dues for the following fiscal year are payable the succeeding January, at which time the treasurer sends a statement to each member. Such members, however, are entitled to The Journal for the full year, even though the membership be not continued.

PAPERS READ AT THE ANNUAL MEETING.

"Every paper received by this Association and ordered to be published, and all plates or other means of illustration, shall be considered the exclusive property of the Association. . . The Board of Trustees shall have *full discretionary power to omit from* the published transactions, in part or in whole, any paper that may be referred to it by the Association or either of the Sections, unless specially instructed to the contrary by vote of the Association." (From Article V of the By-laws.)

NEWS.

Our readers are requested to send us items of news of a medical nature, also marked copies of local newspapers containing matters of interest to members of the medical profession. We shall be glad to know the name of the sender in every instance.

ORIGINAL PAPERS.

Articles are accepted for publication with the understanding that they are contributed solely to this journal.

COPYRIGHT.

Matter appearing in The Journal of the American Medical Association is covered by copyright, but as a general thing, no objection will be made to the reproduction of anything appearing in its columns if proper credit be given.

CONTRIBUTIONS TYPEWRITTEN.

It will be satisfactory to all concerned if authors will have their *contributions typewritten before submitting them for publication.* The expense is small to the author—the satisfaction is great to the editor and printer. We can not promise to return unused manuscript.

Half-tones, zinc etchings and other illustrations will be furnished by The Journal *when photographs or drawings* are supplied by the author.

ADVERTISEMENTS.

Advertising forms go to press eight days in advance of the date of issue. Therefore, in sending in copy, time should be allowed for setting up advertisements and *for the sending* and return of proofs. Advertising rates will be made known on request.

CHANGE OF ADDRESS.

In ordering a change of address it is important that both the old and new addresses be given.

REMITTANCES.

Remittances should be made by check, draft, registered letter, money or express order. Currency should not be sent, unless registered. Stamps in amounts under one dollar are acceptable. Make *all checks, etc., payable to* "Journal American Medical Association," except those for annual dues. These should be made payable and sent direct to the Treasurer, Dr. Henry P. Newman, 100 Washington Street, Chicago.

The Journal of the
American Medical Association

VOL. XXXV CHICAGO, ILLINOIS, JULY 21, 1900 No. 3

Address.

OBSTETRICS AND GYNECOLOGY.*

ADDRESS OF THE CHAIRMAN.
W. E. B. DAVIS, M.D.
BIRMINGHAM, ALA.

It is with much pleasure that I greet you on this occasion. I am grateful beyond expression for the honor you have conferred in selecting me to preside over your deliberations. It is indeed no small distinction to be honored in this way by so important a section of our national association, many of whose members have become known throughout the civilized world by the excellence of their work. No other country has furnished so many leaders in gynecological and abdominal surgery. They form a galaxy of bright stars in the medical firmament, and the history of this department would be incomplete without them. Imagine such a history without the names of McDowell, Sims, Dunlap, the Atlees, Battey and a host of others long since dead, and the many now living who are members of this Association, whose names have become household words. In the language of another, "gynecic surgery, with all its brilliant achievements, owes its position to the illustrious Sims, no less than abdominal surgery owes its origin to the world-renowned McDowell; and the outcome of the labors of these two remarkable men in beneficent results has no parallel in the annals of medicine." Surely we have a heritage which we should prize beyond my power of expression.

I am admonished by the amount of work which appears on the program that the time of the Section will be fully occupied, and have presumed upon your approval of a short address.

OBSTETRICS, GYNECOLOGY AND SURGERY.

It has been claimed that obstetrics has not received the attention it deserves in our Section; that the teachers of obstetrics, with few exceptions, have offered papers on gynecological subjects, and as a result the proceedings have been scant in obstetrical literature. This has not been to the neglect of obstetrics as much as it would appear. Gynecologists have reached the highest perfection in aseptic and *antiseptic technique*. They have emphasized the importance of repairing injuries to the genital tract, and obstetrical operations have been devised and perfected by them. The two departments are so intimately associated that there is little in the one that does not concern the other and that is not necessary for both to know. It has been the application of surgical knowledge that has reduced the frightful mortality of the puerperal state. Such results as have been achieved at the Preston Retreat, of Philadelphia, and at similar institutions in this country and abroad, could not have been attained except by the practice of asepsis and antisepsis, together with such aid surgically as the gynecologist is best fitted to render. Patients in wealthy homes are not so fortunate as the poor in these well-conducted maternities. Physicians who seldom operate, with few exceptions, do not carry out a thorough technique. The habit must be formed. I would feel that this Section had accomplished enough for one session if it could impress upon them that the sterile rubber glove should be used in these cases. There is nothing required that can not be accomplished by the well-fitted gloved hand.

Some years ago the lamented Parvin, in his presidential address before the American Gynecological Society, earnestly pleaded for the combination of the chairs of obstetrics and gynecology in our colleges. He had published with his address a paper by Winckel, of Germany, in which this practice was eulogized. Winckel's claims were based largely on the fact that gynecology in Germany and Austria had been practiced first, with few exceptions, by the obstetricians. This was due entirely to national conditions. The great maternities of Germany and Austria furnish material for the obstetricians to find application for operations which the American, English and French surgeons had proved of value. We as a nation should learn a lesson from Austria and Germany, and have large maternities connected with our colleges for teaching purposes. After this shall have been accomplished, our students will be better trained and results will rapidly grow better in the homes of patients. As stated by Winckel, in all German universities the teacher of obstetrics is also the teacher of gynecology, and the clinic under his direction contains a department for women suffering with diseases of the sexual organs. He says: "A distinct advance was made in 1842, by Kiwisch, of Prague, at whose request a department in the hospital for the treatment of the sexual diseases of women was transferred to his care. Soon after this a similar arrangement was made at Vienna, and by E. Martin in Berlin in 1857; and the last stone in the completion of the structure of general gynecology was furnished by the reception into the same clinic of gravid women and women suffering with diseases of the sexual organs, who were placed, in part for treatment in the wards previously used for the delivery of parturient women, and in part in new buildings constructed for the purpose." Germany is not alone in her position. Throughout Italy the teachers of obstetrics in the universities are the operators in gynecology.

It has been said, "Obstetrics married surgery and the fruit of their union was bright-eyed gynecology." When it is remembered that more than 50 per cent. of the cases coming to the gynecologist for operation are the result of delivery, at term or prematurely, the need of obstetrics for surgery is only too apparent. It may be very justly claimed that the specialty of gynecology resulted from the fact that the surgeon appreciated the situation: and to the surgeon more than to the obstetrician is due the exalted position of this department. I would not belittle the part the obstetrician has played in furtherance of this work, especially in the German and Austrian universities, but it was from the ranks of the surgeons that the first great workers emanated. In return this department, gynecology, has done most to bring surgery to its present high position. The gynecologists have achieved results in abdominal and pelvic work that never could have been accomplished by the surgeon who gave his time to general cases. As in all the special lines of practice and study, it requires a specialist to work out the delicate questions involved in this great field. It has been well said: "Most of the great advances of recent years have been made by them—specialists. They have perfected our methods, enriched our literature and filled our storehouses of knowledge. The reef they are constructing is no longer submerged in the dark waters of obscurity, but is now a mainland teeming with the fruits of their joint labors."

---

*Presented to the Section on Obstetrics and Diseases of Women, at the Fifty-first Annual Meeting of the AMERICAN MEDICAL ASSOCIATION, held at Atlantic City, N. J., June 5-8, 1900.

Dr. Geo. Ben Johnston likens the professional qualities of the true specialist to a massive pyramid, the finished capstone of which constitutes the specialty. "The pyramid of experience, learning and skill is a stable edifice, a pillar of strength which can not topple nor reel. In the case of the pseduo-specialist this pyramid of learning is inverted." Dr. Chas. A. L. Reed holds that specialism is manifestly to be even more distinct than in the past, while specialties, as known to the broad and progressive profession of America, will be able to gain recognition only by conforming to severer tests than are now applied; that it is safe to predict that in the not distant future "there will be fewer specialists, but, happily, better ones." He says: "The lines may, and possibly will, shift. Existing specialties, or certain of them at least, through the influence of further segregation and final equilibration, may, and probably will, disappear into the general profession, while segmentation will be inaugurated at other points to result in the development of other specialties. Thus shall the great future witness the mutations of progress."

Dr. Paul F. Mundé, in 1898, in referring to the growing tendency upon the part of the general surgeon to encroach upon the field of the gynecologist, said: "We all know how long it requires and how difficult it is to gain the *tactus eruditus* by means of which an accurate diagnosis of pathological conditions in the female pelvis and abdomen can be made, and how liable even an expert gynecologist is to err in a doubtful case. How, then. can the general surgeon, with all due allowance for his skill and dexterity as an operator, except to rival the expert gynecologist in the field which the latter has made his special study." He further says that he has seen general surgeons, to whom he would unhesitatingly intrust his patient for an operation in any other region of the body, make woful blunders when attempting to carry out the operative indications emanating from their mistaken application of a purely gynecological case.

The exalted position which gynecology occupies in this country is owing largely to the medical journals devoted to this department, and to the national special societies, of limited membership, whose transactions have gained world-wide reputation. It was a great step when the American Gynecological Society was organized in 1876. Membership in this society meant ability and worth and guaranteed recognition at home and abroad. Later the American Association of Obstetricians and Gynecologists was formed after a similar plan. with like results. In 1887 the Southern Surgical and Gynecological Association was formed. At first this union of surgery and gynecology was questioned by many, but it is acknowledged now by all that it was a fitting and proper union. When this organization was first suggested many thought its sectional name would interfere with its usefulness. Its promoters had no thought of sectionalism. It was formed with a view of giving the profession of the South the opportunities which had long been enjoyed by the East and North. The members of the American Surgical, the American Gynecological and the American Association of Obstetricians and Gynecologists who resided in the South were the ones first to give their support to the organization. Distinguished members of the profession from all parts of the country were invited to join. It was not intended that it should be sectional, but national, in its membership—in other words, it was expected to have its meetings in the South, but its membership from the entire country. The South had done most excellent work, but owing to its scattered population and the war, slavery, etc., her colleges and other institutions were not in keeping with those of the East and North. Many of her surgeons who did splendid work wrote but little and were not known; hence, with but few exceptions, they were not invited to join the Eastern societies. This association looked up the good men throughout the South and brought them forward. Many have since joined the national special associations. But few gynecologists and surgeons of the South who have done good work are members of this society. Its transactions have been complimented at home and abroad. Indeed, it is a fitting organization for a land hallowed by the footprints of McDowell, Sims, Eve, Briggs and Battey. You must agree with me that this Section of the American Medical Association has profited by these special societies. Some have thought to the contrary, but the evidence is too patent to require argument.

PROGRESS IN GYNECOLOGY.

The development of gynecology has witnessed many errors and extremes in practice; but with so many earnest and able workers seeking the truth, it required only time to settle many questions at issue and secure the adoption of safer lines of procedure. Much of Sims' work was found to be erroneous; many of the cervices he slit had to be repaired. Battey's operation was a monstrous mistake; yet the value of his pioneer work in pelvic surgery can not be overestimated. He had no conception of pelvic pathology and removed normal ovaries to establish the menopause, because it had been observed that patients frequently were better after they had ceased to menstruate. I knew Dr. Battey well, and had exceptional opportunity to follow many of his cases. While he thought these nervous cases were benefited by the operation, the unbiased observer could not fail to appreciate his mistake. Think of the countless operations performed by less capable operators than Battey for nervous symptoms, removing normal ovaries. His teachings have resulted in more harm, perhaps, than those of any other one gynecologist. On account of his erroneous and radical teachings the neurologists went to another extreme and have failed to give surgery its proper place in the relief of nervous symptoms by the removal of pathological conditions in the tubes and ovaries. In a discussion before the American Association of Obstetricians and Gynecologists some years ago I made the following remarks, which are pertinent in this connection: "This country, which has been foremost in many good things, and particularly the Southern part of it, has caused much harm in the enthusiasm for surgical procedures for the relief of nervous troubles. Dr. Batey, unquestionably the father of pelvic surgery, did all his operations without any knowledge or conception of the pathological condition to be relieved. In other words, he operated for symptoms. He repeatedly stated that he removed the ovaries in cases which he felt he could not relieve by other treatment. The operation was frequently done in cases where there was no local disease, with bad results, consequently the neurologists became prejudiced against surgical procedures for the relief of pelvic trouble. No doubt the teachings of Dr. Battey have led largely to the prejudice that is manifested now by neurologists. Of course Dr. Battey and his followers were misled in many cases. We know how hysterical women may be operated upon and sometimes relieved, it makes no difference what the operation. An operation on this class of patients seems to relieve for a time even though nothing is removed. As gynecologists, we know that we accomplish the most good in those nervous cases where we find marked pathological conditions. The more local disease we are compelled to remove, the sooner the patient gets well, and the less the disease and the greater the amount of nervous trouble, the slower is the case to recover. Neurologists expect too much in cases of pelvic disease that have progressed perhaps for fifteen or twenty years. If these patients do not get relief at once, the operation is put down as a failure. We might as well expect a man who has had financial reverses, or who has been losing a large fortune for years, to have his nervous system restored at once by the restoration of his money. We know the nervous system does not recover so quickly. Unquestionably, in cases where we find marked neuroses, they are instances in which the women have a predisposition to nervous and mental disease, as has been pointed out by the neurologists."

The French gynecologists, not being permitted for a long time to do abdominal operations, undertook too much by the vaginal route and sacrificed countless uteri and ovaries unnecessarily. In order to reach the pelvis by the vagina it became necessary to remove the uterus to furnish a satisfactory route. A few of these distinguished gynecologists have come across the waters to teach the Americans French methods, and instead have learned that the abdominal incision is the preferable route by which to deal with the majority of the conditions in the pelvis. In their operations for pelvic inflammation they often found themselves unable to remove the tube and ovary after the uterus had been extirpated in cases cured by the operation; yet they did not learn from this that a vaginal section with thorough drainage might have accomplished the same without hysterectomy. Too much has been claimed for vaginal section, yet it has a wide field. Peritubal and periovarian abscesses of large size, from whatever cause, should be drained by this route, and later abdominal section done, if found necessary. The uterus, of course, should be curetted before the abdominal operation. In this way the appendages on one side can in a majority of cases be saved. Puerperal pelvic inflammation occurring in the first month or six weeks after delivery should be dealt with by vaginal incision. If the abscess is small all adhesions should be broken up, and the diseased tube thoroughly opened, followed by gauze packing. A large percentage of such cases will be cured and some will bear children afterward. Cases of puerperal inflammation should be operated on without waiting for pus formation. By early section and drainage convalescence is hurried. My experience in cases without pus has not been large but exceedingly satisfactory.

The extremists for a time advocated hysterectomy for all uterine fibroids that could be found by the most searching examination, and there are some now—the same ones, I believe—who practice myomectomy in a class of cases that the great majority of gynecologists very properly consider suitable for hysterectomy. There is no reason for the sacrifice of the uterus when the tumors can be enucleated without mutilation, but it is mere sentimentalism to try to save organs when greatly mutilated.

Uterine cancer has furnished a field for another extreme in practice. It has not been shown that the extensive operations recently practiced have accomplished more than hysterectomy, going wide of the disease. If it has passed much beyond the uterus, palliative operations are attended with better results than the radical ones. However, I hope that the discussion to take place at this meeting will throw valuable light on the management of these cases.

It is gratifying to note the increasing popularity of the round ligament operation for retrodisplacements of the uterus. I am impressed that few operative procedures without danger are capable of furnishing so much relief. Cases should not be encouraged to wear pessaries when so simple an operation would give relief. If intra-abdominal conditions prevent the extraperitoneal operation the abdomen should be opened and the ligaments shortened by an intra-abdominal method.

Much honor is due Kelly and others for their work in exploring the bladder and ureters, but it is carrying refinement too far when it is attempted to treat pus in the kidney through the ureter. A lumbar incision is too simple and free from danger for such methods.

The surgery of the gall-bladder has advanced little beyond Marion Sims' operation in 1878. No department of surgery has been attended with better results than operation on this organ. While its surgery is about settled, the surgery of the ducts is still under discussion. In the spring of 1893, I undertook some experiments, which I reported the same year to the Surgical Section of this Association, and was convinced from these experiments that it was unnecessary to stitch the duct after the removal of stone; that gauze-drainage and a glass tube would take care of the bile, *even though infected*. This operation *without stitches* had not been done at that time, but since then a sufficient number of cases have occurred to demonstrate the advisability of the procedure. I quote the following from a paper by Dr. W. D. Haggard, Jr., at the New Orleans meeting, 1899, of the Surgical and Gynecological Association, as evidence in favor of the operation:

"If it is inexpedient to suture, the entire efficacy of drainage with gauze has been abundantly proved and its employment ardently insisted upon by W. E. B. Davis. . . . The importance of this suggestion is well illustrated by a recent report. Quénu collected 95 cases of suture of the ducts with a mortality of 35.5 per cent., while the mortality of the cases without suture was only 18 per cent. In these were included six personal cases. In two sutures were used; both died. In two others biliary intoxication appeared, the sutures were cut and the patient recovered. The other two were not sutured and recovered. Fenger also believes the common duct should not be sutured as a rule, and never without drainage, both from the site of incision in the duct, and particularly drainage of the gall-bladder to prevent biliary intoxication."

This procedure should make the surgeon feel very secure in these operations, as it is almost impossible to stitch the duct satisfactorily in many cases.

The methods of stitching the abdominal incision have not proved entirely satisfactory. Animal sutures may give way, causing trouble, and non-absorbable material, if buried, may have to be removed. I have been using a method which commends itself in a considerable percentage of cases. The tier suture with absorbable material has a high place in surgery, but the majority still close the wound by the interrupted through-and-through suture of non-absorbable material. The method described possesses the advantage of both, and obviates some of their objectionable features. I use interrupted sutures of silkworm gut, uniting the aponeurosis, recti muscles and peritoneum, and secure the sutures by means of very small silver tubes, corresponding in length to the thickness of the skin and subcutaneous fat, through which the ends of the suture are passed, and then through a perforated shot. After the aponeurosis has been well approximated, each tube is pressed well down and secured by the compression of the shot at the distal end of the tube. After all sutures have been secured, the skin is brought together with a very small suture of silk or catgut. The suture should be very superficial or subcuticular. The little tubes with shot project just beyond the wound. Compresses of gauze are placed on the sides of incision to approximate the subcutaneous fat.

The silkworm gut sutures should remain from two to three weeks, and may be removed by clipping the ends of the suture between the tube and the shot, and after the tube is removed the suture comes without difficulty. By this method the wound is free of all foreign material before the patient is discharged, there being nothing left to cause subsequent trouble. The method has a wide field of application.

In conclusion, I may say we have reason to regard the future of this Section, and of the Association of which it is a part, most promising—in fact, brighter than ever before. Much has been accomplished in making the editor of The Journal secretary of the Association. There yet remains one source of regret to all, and that is that the New York State Medical Society is not in affiliation with the Association. Let us hope that the time is not far distant when it shall be otherwise.

A SYSTEM OF PERSONAL BIOLOGIC EXAMINATIONS THE CONDITION OF ADEQUATE MEDICAL AND SCIENTIFIC CONDUCT OF LIFE.*

BY GEORGE M. GOULD, M.D.

PHILADELPHIA.

The ranchman has his annual round-up; the merchant his yearly account of stock and balancing of books; the machinist gives his engine a thorough going-over at regular intervals; every military organization has its reviews and inspections, every government its budgets—indeed, every financial hair of the commercial head is noted, and not a sparrow of the hunter, Success, falls to the ground unnumbered; those that do not fall are even more accurately numbered. But it is not so concerning the one piece of mechanism that conditions all these things, and that is the most valuable of all earthly possessions—the human body. For all practical consideration a man's body is his life, and yet civilization has come so far without any systematization of the business and mechanics of the entire single and personal life. The science of bodily living in its complete extent still awaits its discoverer. Numberless philosophers treating of the conduct of life have soared in superficial inexactness and easy generality over the heads and hungers of the individual liver, but they have utterly failed to formulate the physiologic and pathologic conditions of success and failure. All the biologic and medical special sciences have struggled toward an unreached unity; all are single rays, as it were, awaiting the lens of a focalizing intelligence to illumine the concrete image of our total physical appearance here. War has devised a rough and crude system of physical examinations for the would-be soldier; insurance companies have more accurately examined the bodies and life-prospects of their policy-holders to estimate their financial risks; through the Bertillon system, criminology has still more perfectly fixed the anatomic measuring of the bodies of the lawbreaker; the Amherst and Harvard examinations have looked into the muscular functions of a few students for four years of their lives; the psychophysic laboratory has measured a few neurologic reactions; the medical practitioner has found out a few ways of reaching backward to the etiology of some single diseases; a few hundred school children have been subjected to some tests as to growth and the influence upon organization of poverty and wealth. But all these, I believe, are sporadic and ineffectual hints of a coming science of man, based upon a thoroughgoing and repetitive system of physiologic and pathologic examinations which will ultimately give us a genuine and all-comprising science of anthropology based upon all the data, morphologic, physiologic, and pathogenic, of the entire individual life. Prophecy and prognosis are based upon a thorough knowledge of the past and present fact, a rigid understanding in a scientific sense of the evolution of the organism and of its present departures from a normal standard. For his children a foresighted man must wish such an accounting, such a prophecy and prognosis; and as to himself every intelligent adult, when he awakens to scientific consciousness, must try to look forward through the years, and reckon up his powers and possibilities of life. This most important function of prevision has heretofore been left to the gypsies, the palmists, the astrologists, and the clairvoyants! Is it a wise way for science to leave the individual struggler, unconscious and ignorant of his own body and its fateful laws, incapable of learning the scattered and ununified half-sciences blindly converging to some far-off unity of mutual helpfulness and life? The crowning work of scientists is to turn science into prescience. The unification of the sciences dealing with the conduct of life; the making practical and useful our knowledge of the individual organism; and lastly to establish a scientific prescience—such are the ideals of a living anthropology.

Is it not at once plain that these ideals can be realized only by a system of periodic examinations and records made every year or every five years, throughout the life of the individual organism? Such a system of records may be held generally to comprise the following elements:

---

*Presented to the Section on Practice of Medicine, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

1. *The hereditary datum.*—The endowment at birth, the influence of heredity, must in every way govern and condition the development of the organism, and modify every reaction to environment. It is wise therefore in all ways possible to fix, at the opening of life, what is this datum of inheritance. Nationality, ancestral and genealogic histories, craniology, cerebrology, etc., help to make up the estimate of this factor.

2. *The developmental and historic record.*—Especially during the period of growth—childhood and adolescence—should the space between the annual or quinquennial systematic examinations be historically epitomized. The strains, work, illness, and tasks conquered or incomplete, are surely a necessary part of the life-chronicle.

3. *The morphologic or anthropometric examination is fundamental.*—In this the Bertillon system, modified, perfected, and expanded, or something similar, should form the basis of such a system of physical measurements, descriptions, and records, statistic and graphic, that any future variation of the organism would be detected in later examinations; and thus would be preserved the morphologic picture of the individual for the whole life.

4. *The physiologic record* would include the testing and tabulation of all the significant reactions and functions. These would be made up of all necessary dynamic tests of the muscular system; of statements of accurately observed metabolic and nutritional functions; the reactions and reflexes of each of the special senses, and of those of the neurologic and psychophysic systems. The profound influence of habits, both positive and negative, innocent or harmful, should also be remembered.

5. *The psychic or intellectual datum* is one too carelessly ignored in scientific and anthropologic studies. The fundamental qualities of character, disposition, memory, sentiment, religion, reason, morality, education, etc., are powerful influences acting upon and reacting to the environment and to disease, and if they are left out of the count a most valuable determinant of scientific prescience is lost.

6. *The pathologic element* is one heretofore almost or utterly ignored in anthropologic studies, and in instructions as to the conduct of life. The profession should urge its profound importance. The examinations at stated periods should in large part consist of the records of the findings of expert medical specialists secured by all the arts and instruments of diagnosis at their command. All departures from health and normality that indicate pathologic results or tendencies in any organ, or in the organism as a whole, are absolute conditions of estimate as to present powers or prospects. One is almost inclined to think that the savings in medicolegal cases, by such a system of examinations, would defray the expenses of making them. Some time ago a railway company, after several years of legal proceedings, was forced to pay a man $10,000 damages for intracranial hemorrhage said to have been caused by a fall from a car. When the man died there was found in his brain a bullet which had been received 25 years previously in the Franco-Prussian war, and this had produced all the non-feigned symptoms for which the railway had to pay.

7. *The factor of heredity* closes the circle, with the possibility of making more accurate the knowledge of the transmission of the individual endowment to the child. Successive generations are but the completion and extension of a single personality. The family is the realization of the incomplete individual.

Leaving out of consideration the questions of the onerousness of the task proposed, and the apparent impossibility of carrying out so many observations, one may ask as to the feasibility of keeping the records of such a series. The answer to this query points to the most remarkable plasticity and adaptability of the modern plan of record-making by the card-system, with its ever variable and extensible use of loose leaflets or cards of different colors, numbers, ear-marks, sizes, etc. Photography, the kromscop, the phonograph, the instruments of the physiologic and psychophysic laboratories, and those of every specialist in medicine, make it easily possible to condense the chronicles of all tests and examinations in an inexpensive and effective way. The post-mortem records, and the preservation of the brains, and, perhaps, of the skulls of the subjects, would supplement the work.

As has been intimated, we already have the beginnings, the sporadic attempts, and detached parts of such a system of examinations. The Bertillon criminal records of the police bureaus, the anthropometric data of military examinations, the results of athletic and gymnasium tests, those of psychophysic laboratories, the medical examinations of school children, and those especially of life-insurance companies, etc.—all these indicate the thought, labor and expense which civilization is giving to the problem. But the most important of all contributions might be the case-books, hospital records, and patients' histories of physicians. Hardly a tithe of the precious material, however, is utilized The waste of biologic data—wasted because not systematized and unified—in the lost records of physicians is appalling. The most valuable books in the world are the oldest city directories, scientific statistic records, etc., and more valuable still would in future years be the present-day case-books of scientific physicians, if they were well kept and illuminated by a statistical and scientific judgment. We now dump them into the pulp-mill.

Is it a foolish dream, is it an unrealizable ideal, that all these things might be preserved, and rendered of use to science and humanity by some institution carried on by the government, by a university, or by a union of scientific and medical men, whereby the records of individual lives might be made so frequently, so continuously, and so scientifically that we should at least gather the inductive data for a genuine science of anthropology, pathology, and ethical biology? If governments could be prevailed upon to devote to this work one-tenth the money now squandered in war; if legislators could be prevailed upon to give to it a small proportion of their stealings and political plunderings; if a fraction of the money poured into the pockets of the ward and city bosses could be got; if a small percentage of that spent on comic opera could be shunted this way! If these are idle dreamings is it not perfectly possible that in future ages some wise legislator of some civilized government may convince his fellows that not only is this the duty of the national administration, but that the very beginnings of the system are already in operation in the national census-taking. In this the mechanism is really inaugurated, and needs but the inclusion of the civil service examination, the soldiers' entrance tests, and the governmental pensioners' medical examinations, to bring it a long way toward perfection. With the plan once determined upon, and the brain once found to gather the haphazard and discrete parts to an organic unity, but little additional expense would be incurred over that now spent in the separate systems. Indeed, the scheme itself is only an extended and a perfected bureau of vital statistics. Once such co-operation were started, the city and state with their criminologic statistics, the insurance companies with their accurate vital and pathologic records, and especially the medical profession with its systematized records of individual and social morbidity, and many other agencies, would be drawn into co-operation, and the bases of a truly inductive and physiologic science of civilization would begin to be laid.

While we wait for that millennial palace of Science we physicians need not be idle—nay, we may be at work in the quarries. Our first duty is to reorganize, systematize, and make scientific our case-books and recordings of patients' histories. Let us study this great and neglected art so that these most precious fruits of our life-work shall not end in the pulp-mill. The lack of literary workmanship in making and keeping our records of disease is altogether deplorable. What is left to science of the life-work of a million physicians whose business has been with the most precious biologic facts of the world? Can we not perfect some bridge whereby the results of our life-labors can be carried over the stream of death and become the property of general biologic and pathologic science?

Surely then, our second duty is to make our science prescient, by means of the repeated examination at stated intervals of those patients whom we can convince of the necessity and wisdom of such a proceeding. It is a shame of medicine that in the one department of our science which we are most foolishly inclined to look down on with too much superciliousness, its practitioners have outrun us. The dentists have long recognized the need of periodic examinations of the special organ, regardless of symptoms, and they have at last driven the knowledge into the minds of their patients. Thousands of patients have their teeth periodically examined for beginning needs and diseases or to prevent them. If this be wise as regards the teeth, how infinitely wiser it would be as regards the kidneys, the eyes, the heart, arteries, etc., and the person as a whole. It is the shame of medicine and the basis of quackery, this symptom-treating and symptom-killing. What a horrible fact—this of the vogue of the pain-deadeners! Millons of dollars are capitalized in the business, and half or three-fourths of the work of our lives is devoted to the mere stopping or deadening of symptoms. But, as we all know, true medicine is to stop the cause of symptoms, to prevent the symptoms from ever arising. For many years, in my specialty, I have been begging that biennial ocular examinations should be made, regardless of "no trouble," regardless of "perfect satisfaction." Absence of symptoms is no evidence whatever of absence of disease. No eye should ever be left over two years without re-examination. No spectacles can remain correct two years, because no eye ever preserves the same refraction, balance, and powers, for that period of time.

And what good also is the enucleated eyeball, or any piece of dead tissue. in the hands of the pathologist? Certainly only to prevent other living eyes and organs from becoming as these dead ones have. True pathology is surely knowledge of disease in the making. The pathologist's final problem is to prevent pathologic specimens from ever coming into his hands. Quâ pathologist he must commit scientific suicide. Most of our fashionable pathology is the paleontology, not the biology, of disease; but was it not said of old, that it is better to be a living dog than a dead lion? How is disease in the making ever to be discovered except by examinations, continuous observation, of the living supposably-well organism?

Is it not even true of living disease that one-half the patients seen by the doctor are seen far too late? For paresis, locomotor ataxia, etc., and for many psychic diseases we do nothing, because we recognize their existence so late that nothing can be done. Had they been seen earlier injury could have been prevented. Surely in more than 25 per cent. of my patients many years or whole lifetimes of suffering and disease could have been obviated. It is doubtless as true in general medicine. All good medicine inevitably tends to become preventive medicine; all good physicians labor to stop disease before it arrives. The whole ingenuity of the trained diagnostician is now expended on the problem of the earlier symptom. He is the greatest discoverer who finds the presymptom, or the symptom of the symptom; the greatest therapeutist is he who cures before the disease exists, he who starves the bacillus to death, he who stops the evil habit, thus preventing the malfunction that becomes organic disease. The best cat is the one that kills the rat that eats the malt that lies in the house that Jack built. It is a truism that gout exists in the patient's system long before it causes a twinge of pain; the kidneys are ruined before the slightest subjective system is manifest; there may be heart changes indicating the existence of nephritis, which a single uranalysis may not detect; arteriosclerosis may be present prior to subjective symptoms, and the objective examination would detect it; there may be unsuspected diabetes without symptoms until examination of the urine reveals it—even with our crude prescience early uranalysis of the apparently well would often reveal the hidden evil at work sapping and mining toward the vital centers. Every oculist has often discovered albuminuria before the general physician suspected it. There are a hundred known intimations and auras of oncoming disease, but there are a thousand undiscovered ones, presymptoms, advance scouts and forerunners, to be learned when the slight and unconscious departures from normality are studied by examinations of the supposably well. Pathogenesis, not therapeutics, is the ultimate study of all medicine. And all pathogenesis is by no means running bugs to their holes: the greater number of life-wasting diseases are not bacterial in origin; and even the growth of the bacterial diseases depends on the soil in which they are sown.

I picture to myself a new field of work opening out before the poor plundered general practitioner. It must often seem to him that as a general he has been stripped of both army and enemy. One by one the specialists have robbed him until he has left hardly a soldier or a patient. The surgeon first took almost half of his army, and now threatens to relieve him of Colonels Appendicitis and Typhoid, and heaven knows of how many more officers which he formerly considered his very own. Then the aurist, the oculist, and the rhinologist deprived him of his special senses, and the laryngologist rendered him aphonic. If the obstetrician and gynecologist left him one or two of all his women folk, the rest-cure man and the neurologist soon alienated the affections of these hysterics—and they lived unhappily ever after. The pediatrist stole his babies and the psychiatrist his mind; and, lastly, the gastrologist will not allow him to have all to himself, even a simple stomachache.

The truth seems to be that of all the specialists the generalist has been squeezed into the narrowest specialty, and the surgeon is grasping avidly at his one or two remaining comforts. Even the diseases of the lungs, stomach and kidneys are now claimed and we may soon expect to see such advertisements in the religious and daily newspapers as: "A new operation for neurasthenia; craniotomy for unselfishness; preventive inoculations in case of threatened breach of promise; vaccinations for antivivisectionists; damaged heart-valves surgically repaired while you wait; kidneys transplanted immediately following the next electrocution; complete maturation of the artificially fertilized ovum in our new twenty-first century incubator."

The family physician's function seems to be fast becoming that of adviser-in-general and referrer-to-others; the "last straw" is that ethics will not permit these others to divide their fees with him. Nothing in fact is left to him except to have permanent anorexia and to move to a climate in which house and clothing are not necessary—Porto Rico and the Philippines, for example—providentially supplied, without doubt, for this and similar tariff purposes.

But seriously, have we not gone too far with our specialism, and are we not thereby in danger of losing the co-ordinating sense and oversight of the organism as a whole? The specialist can not be dispensed with. By his aid and through his accuracy medicine must progress; but neither should the generalist be squeezed aside. He is even more necessary. It is his duty to teach his under-officers, the specialists, their proper places, and by his sane and large grasp of all the facts supplied by these subalterns, by his co-ordination of the work of each and of all with his own overlook of organism and life as a whole, he brings cosmos out of chaos, and organic unity out of hundred-eyed and selfish diversity. The specialist is fatally inclined to treat the disease; to the generalist must be left the far more important treatment of the patient.

It may seem hard and impertinent to say to an audience of generalists that the generalists have been robbed because of their own fault and negligence. The so-called stealings of the specialists are in reality helpful and if rightly understood they leave the generalist his proper work. Life, it has been said, is made up of little things; and yet life itself is not a little thing. So it is with health, fulness of years, and utilization of powers; they all depend, medically and physiologically, upon little things, and yet compositely, they are "the greatest thing in the world." In the vogue of the specialist, the generalist is more than ever needed. If the aristocrats have usurped power, there is the chance and demand for a powerful king. The specialists are, or may be made, the assistants of the general physician, who needs their help and all the data they can supply, and whose supreme function it is to fuse the whole to a higher unity and to establish the secret relations in reality existing in all. There is no specialist who is not willing and glad to make full and systematic reports to the general physician of all his findings. It is his duty to the patient and it is the specialist's self-interest to do it well. He is not so stupid as to offend the referrer of patients. In this function the generalist has the whip-hand—and he should use it, at times.

And thus it happens that the desirable system of personal biologic tests sketched need not await the action of government, the university department, the city or state institute, the union of anthropologic societies, or the anthropometric and pathologic institution founded by private endowment. Let us earnestly pray and work for any or all these things; but in the meantime much may be done by medical men and societies to prepare for the larger and more perfect outworking of the scheme—nay much may be done toward the realization of its more distinctively medical features.

Based upon the fact actually felt by every physician, that a series of systematized periodic examinations of patients apparently well would often reveal beginning diseases, prevent future illnesses, and increase the vital values of life, every one can prevail upon certain patients, students, or members of his family, to undergo the necessary tests. The more intellectual and well-to-do citizens will soon realize the self-evident value of such work, and not only submit to it for themselves and children, but will be willing to pay an annual fee for the service. Specialists will be willing to contribute their results. The examinations need be only of the more fundamental and simple factors at first until the good-will, machinery, funds, and recognition of the significance and usefulness of the work grow.

In several ways these examinations themselves are the means of a striking self-education of the physician:

1. In systematizing and perfecting a method of record-keeping there is a subjectively psychologic as well as an objectively scientific result of inestimable good. It is a sort of liberal education. To adapt and perfect the card-system to this useful end; to summarize the results of all diagnostic methods; to formulate prognoses; to classify and epitomize so that the whole shall look to the personal advantage, as well as toward the progress of preventive medicine; and finally, to dovetail the combined result into general biologic science and to clarify the laws of heredity; all of this is labor worthy of the wisest selfishness and the best intellectuality.

2. In rendering accurate and mathematical all the known and recognized methods of medical testings, there is much to be learned. It is in catching sight of the forerunning indication of disease, the symptom of the symptom, the functional beginnings of organic abnormalism, that a large deal of progress lies. Who, e. g., as yet, measures the blow or stimulus in taking the patellar tendon and other reflexes, with machine-shop accuracy, also the resultant excursion or reaction, chronicling same in his notes, with absolute or approximate precision?

3. In the excursions into the border land, but still closely related, domains of cerebrology, craniology, psychophysics, criminology, sociology, public hygiene, and all the rest—in learning to make these tests, and chronicle the results required in these studies, one enlarges the range of his subjects, broadens his personal and scientific outlook—in a word annexes with justifiable i[illegible]ri-alism and expansion, the adjacent t[illegible] [illegible]f [illegible]-cial science. Each gives his light, [illegible] cence, by giving, each increases h[illegible] general illumination. The stars [illegible] dawns.

DISCUSSION.

Dr. Charles G. Stockton, Buffalo, N. Y.—This most interesting paper of Dr. Gould is one which I should like to think over a while before discussing it. Its importance is manifest, and its applications are many. Without attempting to go into the subject at length, I desire to mention this suggestion, which was made to me years ago by another, viz: that it would be possible to establish archives of individuals and family histories which might be placed on file, as documents are now kept at the office of the county clerk. While this may be impracticable, if it could be accomplished it would be a good thing, and would enable us to solve many of the questions relating to heredity.

LARYNGOLOGY AND ITS RELATIONS TO GENERAL MEDICINE.*

J. SOLIS-COHEN, M.D.

PHILADELPHIA.

Laryngology is more intimate in its relations to general medicine than is fully realized by the average practitioner, or by the exclusive specialist.

Except by the initiated few, the laryngoscope was regarded in the earlier days of laryngology as little more than a physiological toy; but the lessons learned and the triumphs earned by those few, and by their pupils, their successors and their admirers, have slowly become sufficiently appreciated to render its more or less systematic study necessary in well-appointed schools of medicine. Indeed, in a number of medical schools, in the United States at least, laryngology, with its collateral subjects, is the students' favorite among the elective branches. Nearly every school has one professorial instructor with his staff of assistants; some schools have two, and at least one has three. This demand for laryngological instruction must soon culminate in its acknowledgment as an essential feature in medical tuition, requiring satisfactory examinations in efficiency as prerequisites to medical degrees. Teachers of the branch should uphold its dignity and aim for this complete recognition. Nothing less can be assigned to this important region where cross the two essential avenues of life, the pathways to respiration and nutrition.

THE LARYNGOLOGIST SHOULD HAVE A KNOWLEDGE OF GENERAL MEDICINE.

What has been the cause for this great desire for instruction in diseases of the upper air-passages and accessory structures? Partly, perhaps, a wish to participate in the reputed pecuniary rewards of those who have been devoting themselves to laryngological and kindred practice. Largely, more probably, in the gradual comprehension by preceptors and practitioners generally, of the manifold relations of this branch with nearly every other branch of medical practice, and the light and more light which it is steadily casting upon obscure points in the broad domain of general medicine. This leads them to recommend the study of the throat and nose to their medical students, as an essential branch of their professional education. For this reason, it is in all probability a great error for a recent graduate to devote himself to exclusive practice in a special line before he has some considerable experience in general practice. A general practice, with special attention meanwhile to any desired branch, will render the practitioner the better and more thorough specialist in the long run. There are specialists and specialists. There are specialists in the branch under consideration who rarely, if ever, condescend to feel a patient's pulse or in any other way make themselves acquainted with the condition of his general health. Mechanicians rather than physicians, they will snare or cut away or otherwise remove an obstructing turgescence of a turbinate body, when a smart saline laxative would have purged the tissues of their excess of liquid, or when even a run upstairs from the bottom of the house to the top would have sent blood enough to the patient's heels to lessen the supply to his head and thus restore nasal respiration for the time being. Then again, ignorance of the relations of the nasal structures and accessories to the structures of the ear, to the structures of the eye, and alas! to the structures of the brain, occasionally leads to the sacrifice of an organ or of a life to injudicious instrumental operation, and occasionally even to injudicious instrumental explanatory investigation. So, too, ignorance of possible sequence to operative interference engenders neglect in attention after operation; and again organ or life becomes a sacrifice to hemorrhage, to autoseptic infection, or to some unexpected complication. From these errors the specialist who remains or has been a general practitioner is far more free. He is in the habit of, actually or mentally, interrogating more or less the entire system of his patients, and of providing for exceptional contingencies; his errors are more likely to be errors of judgment than errors of ignorance; in the other case, the errors are errors of ignorance as well as errors of judgment. Often, too, the ignorant specialist is so unaware of his deficiency that he vaunts as great personal triumphs the eventual subsidence by exhaustion of tumultuous complications, really brought about by his own injudicious interference.

RELATION OF LARYNGOLOGY TO OTOLOGY.

In briefly enumerating some of the more prominent relations of laryngology to other medical departments and to general medical practice, the diseases of the ear produced by extension and convection occur first in consideration; and so closely has the connection been demonstrated that prevalent opinion coincides to-day with that expressed by the writer of this address a generation ago: that diseases of the ear could not be properly cared for without familiarity with rhinopharyngology, and that treatment of diseases of the ear should be practiced in connection with laryngology rather than with ophthalmology, as was then the almost universal custom. These relations are so familiar to the members of this Section that they need not be further alluded to.

RELATIONS BETWEEN RHINOLOGY AND OPHTHALMOLOGY.

The relations between rhinology and ophthalmology are not so close; but there are numbers of positive relations. Beginning with conjunctivitis, many an intractable case can be cured by treating the preliminary nasal catarrh which has extended along the nasal duct. Then there are the diseases of the lachrymal apparatus, sometimes due to direct pressure from hypertrophied, abnormal or distorted turbinate or septum; or from polyp or morbid growth; or from mere atrophic rhinitis without any stricture of the canal whatever. Then there are the distortions of the orbit produced by abscess and neoplasms in antrum and nasal structures. Furthermore there are remoter relations with retinal and other defects, with which most of us are far less familiar, and which have been reported chiefly as contributions to ophthalmologic literature.

RELATION OF LARYNGOLOGY TO GENERAL MEDICINE.

Passing to general medicine, where in its study will be found better places to observe the natural history of circulatory phenomena in the mucous membranes; anemic, passive or congestive; ecchymotic, infiltratory, inflammatory or ulcerous; than just in those places exposed by laryngological aid, or to follow the clinical progress of specific and other infectious processes, of morbid growths, or of tuberculous infiltration? In the opinion of the great Virchow, "the larynx is the very best place to study tubercle." So likewise the corollaries of many dermal diseases are seen in these mucous membranes modified by difference of structure, sometimes as though developed in the sodden skin. Here again will be seen the manifestations of the exanthematous diseases in advance of their cutaneous evidence. In this region, too, diphtheria is first detected, often happily in time to avert all perilous constitutional involvements. Anemia of the laryngeal mucous membrane may be the first manifestation of constitutional tuberculosis; epiglottitis, the first symptom of enteric fever, and edema of epiglottis and larynx, the first suggestion of renal insufficiency. Nephritis and diabetes are sometimes first suspected by the evidence disclosed on laryngoscopic investigation; and the advanced stage of the latter malady is sometimes indicated by ulcerative processes attributable by exclusion to no other systemic condition.

---

*Presented to the Section on Laryngology and Otology, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

Laryngologic inspection and the sequels of topical treatment of diseased conditions under its aid, have taught us that much which is deemed rheumatism is really infectious arthritis, infectious myositis or myalgia, originating in bacteriological changes in the mucous membranes and glands produced by disease or by interference with disease, and projected along lymphatic or circulatory channels to structures at a distance. This lesson demonstrates the importance of hunting within the diseased body for processes actually autotoxic, instead of speculating too much upon the introduction of toxic processes from without.

This brings to mind how much laryngorhinology is contributing to bacteriologic studies of great import to general medicine. The various organisms found normally in the different cavities and their adnexa in health; the metamorphoses taking place in many of them under various exposures and under the influences of various systemic diseases; the introduction of foreign bacteria under climatic and infectious influences and the changes that these undergo, can be well studied in the domain under consideration.

Respiratory diseases are largely sequels of rhinopharyngeal and laryngeal disease, sometimes by direct extension, as in chronic bronchitis, sometimes by obstruction, as in emphysema, sometimes by reflex neurosis, as in asthma. Round shoulders, pigeon breast, deflected spine are often the sequence of impaired nasopharyngeal respiration, and most frequently consequent upon the presence of lymphoid enlargements at the vault of the pharynx.

DISEASES OF THE CENTRAL NERVOUS SYSTEM.

The close circulatory relations between intranasal structures and cerebral meninges are sufficiently intimate to admit of transference of morbid products and traumatic injury from one region to the other; and thus serious cerebral complications, structural as well as functional, may follow in consequence of disease in the rhinopharyngeal regions.

Doubtless some of you have had the gratification of saving patients from commitment to insane asylums by correcting or curing some intranasal or rhinopharyngeal lesion; or have rescued an inmate from an asylum for idiots by wrenching lymphoid hypertrophies and proliferations from the fornix of his pharynx.

DISEASES OF THE PERIPHERAL NERVOUS SYSTEM.

Turning now to the peripheric nervous system, allusion may be made to frontal and other headaches, to asthma, to repressed and impaired intellection, to night terors, to convulsions, to epilepsy and to insanity, directly due to intranasal and pharyngeal disease, and upon the removal of which depends the cure or the best possible measure of relief whatever it may be, but in either instance unattainable by administration of neurotic drugs.

Some cases of special neural diseases, central and peripheral, are to be suspected or detected in their earlier manifestations solely by laryngological investigation. Thus bilateral paralysis of the adductor muscles of the larynx is often the first intimation of a progressive locomotor ataxia; and its recognition sometimes suggests the only method of securing immunity from the risk of sudden death by spasm of the larynx. Unilateral paralysis of the recurrent laryngeal nerve is often the very first and sometimes the sole method of recognizing the existence of an aneurysm of the aorta; as it is often the first intimation of the development of esophageal and other intrathoracic neoplasms.

Thus without going further abroad to hunt up analogous examples, it must be admitted that the whole domain of medical practice may be more or less intimately associated with primary lesions in its laryngologic and rhinopharyngologic territory; this but emphasizes the thought in the development of which this address was begun, namely, that the practitioner of diseases of the throat and nasal passages should be at least competent to practice general medicine, in order to do justice to his specialty and to contribute the best that his specialty has to offer in the interest of his patients.

1824 Chestnut St.

HUMAN TEMPERATURE IN DISEASE.*

NORMAN BRIDGE, M.D.
LOS ANGELES, CAL.

We are always seeking for symptoms that tell the exact nature of the diseases of the human body. If there were idiopathic signs the people would learn many of them, and hardly need doctors, except for the mysteries of treatment; and even these they would more or less master in time, as now they often think they have mastered them. The doctors are alert for the smallest hint of a new sign that can show without error the goings-on in the sick body. The treatment of disease troubles us rather less than the diagnosis; and we are usually more chagrined at our errors of diagnosis than at blunders of treatment.

The temperature of the body in health is maintained at a given point, with slight fluctuations, in all climates and conditions; and it fluctuates peculiarly in disease, and probably with some approach to a typical manner. How these mutations may be discovered and so the clinical thermometer be made more effective in practice has been a long search of the profession.

The temperature of the body in health is kept near a normal line by a regulating mechanism somewhere in the nervous system. More heat is usually made b
cles and glands than is necessary, and the
point is chiefly maintained by varying loss of

---

*Read before the Association of American Physicia
ton, D. C., May 3, 1900.

mostly to the changing size of superficial vessels produced by the muscular fibers in their walls. These fibers are controlled by nerves, and so by nerve-centers.

In fever there is a regulation point as truly as in health, only it is higher and less constant. With its rise and fall there are frequently attendant symptoms that are curious and paradoxical, although probably conservative, as the subjective sensation of cold with a rising temperature and of heat with a falling one. It is not true that more heat is generally produced in the body in fever than in health under full exercise, but the contrary. It is only the regulation point that always rises.

What makes the regulation point rise? Why do the nerve-centers controlling the heat manufacture and dissipation change their force and action under certain influences which we call causes of disease? These questions go at once to the core of the clinical phase of the subject.

Doubtless several pathologic conditions produce the rise of the regulation point, and the accidents to these factors may cause all of the fluctuations. There is no great change in the regulation point below the normal; whenever, therefore, we speak of a change we mean a change above the physiologic par, and that is fever. Yet there are disorders, of a chronic sort mostly, in which the temperature is for weeks or months slightly below normal at certain or all times of the day. Myxedema is one of them.

The tendency of professional thought is now toward attributing all fever to certain substances in the blood produced by microbes or to the microbes themselves. The proof of such toxic influences is overwhelming, but they are not the sole causative forces. And if we shall ever be able to catalogue all the causes we shall need to discover the one essential factor in the complete solution of the question—namely, the manner in which the nervous regulating machinery is ultimately affected by toxins or what not.

In studying the fluctuations of temperature we may profitably set a few things we know over against some that we do not know, and so hope to gain some practical lessons for the more efficient care of the sick.

1. We know that pus poison—that is, the microorganisms of pus and their products absorbed into the general circulation—causes fever. We probably often encounter fevers that we fail to understand, which are due to small accumulations of pus hidden away somewhere in the body; but that is no justification for the assumption that in every inexplicable prolonged fever such a source of poison must exist.

2. Dead tissue, as the products of changes in greatly overworked muscles, albuminous bodies set free from these tissues, and floating in the blood, probably cause fever.

3. Slight elevation of temperature is produced by absorption of albuminous toxic substances from cyst cavities in various portions of the body, as the skin, the scalp, and the ovaries, that leak into the connective tissue about them and undergo absorption. These are not the products of pus poison.

4. Then we know that certain poisons, almost positively microbic, are taken into the body from the air, or in food and drink, and produce fevers—with possible eruptions upon the skin—which run a distinct course and terminate spontaneously if the patient lives. The fever begins after a period more or less definite—an average of perhaps a week—of so-called incubation, and often begins suddenly. Probably a certain amount of the poison must be introduced to cause fever, or some especial susceptibility must exist to make possible the cycle of events referred to. The theory seems plausible that the self-limitation of these diseases is due to the rapid accumulation in the body of the products of the microbes, first depressing, then destroying them; or that the microbes, by some reaction of the physiologic forces of the system, provoke the formation of a toxin capable of destroying them in a few days. This class of diseases includes, of course, typhoid, typhus, scarlet, and yellow fever, measles, German measles, whooping-cough, varicella, variola and its modifications, pneumonia, plague, diphtheria, erysipelas, follicular tonsillitis, possibly acute rheumatism, and unnumbered other and yet unknown diseases. The list is not complete, nor will it be probably for many decades to come. We shall go on, as we have done, discovering new diseases out of the symptoms that have been the common but misinterpreted observation of centuries.

5. We know that high temperature results from certain conditions of malarial organisms in the blood, the forms of fever differing with the life-history of the plasmodia. Here, too, personal susceptibility plays some part in the process; all people do not resist or succumb alike, nor do all who are affected suffer alike, either in manner or degree.

6. High temperature of the environing atmosphere, with or without the sun's rays, under certain conditions causes alarming pyrexia known as thermic fever or sunstroke. It is probably due to inhibition or stimulation of some of the heat centers or other part of the heat-regulating machinery. But microbes have even been accused of inducing these cases, and it is not very unlikely that toxins are produced in the tissues by the heat and disturb the regulating centers, and so cause fever as the toxins of bacteria do.

7. We know that inflamed follicles of the tonsils may cause sudden high temperature, lasting a few days and subsiding spontaneously, while the same sorts of microbes are found within them that are discovered in normal follicles. How far this fever should be attributed to pus poison is unsettled.

8. Inflammations in general are attended with fever. Formerly we thought they always produced the fever; but now we know the two events are frequently coresults of some other causative influence. Where some irritant, applied locally, depreciates the vitality of a part, and inflammation results, and then fever, it is rational to assume that the microbes of pus may find there a culture-medium, and infect the system as they do from an abscess. But when, as in the pneumococcus infection, we know a fever precedes the inflammation in the lung, it is clear that the microbe poison in the blood does the whole mischief. And nobody knows how much of some toxin may find its way into the circulation as the result of an inflammation and help to cause fever.

9. We know, but usually forget, that the commonest serious diseases of the kidneys are free from fever as well as from backache; that practically no disease of these organs causes fever save the rarest and somewhat questionable acute parenchymatous inflammation of the renal or the perirenal tissues, and that in general only those with calculi cause pain in the back. Bright's disease fails to do either in any of its multifarious forms.

10. We do not know how much fever is caused by tuberculosis apart from that due to pus microbes encouraged to grow by the tissue necrosis, which is nearly always induced by this remarkable disease, and to absorption of products of the necrosed tissue itself. Pure

tuberculosis may, but usually does not, cause fever under circumstances that permit us positively to exclude the presence of pus products or those of inflammation or necrosis, whatever they are, except where the tissues of or about the central nervous system are directly involved.

11. We do not know why fever rises or falls rapidly or slowly. There are ingenious theories about it, but no proof.

12. We lack positive information to explain the genesis of many cases of fever which occur suddenly in children—and occasionally in adults—and are connected in some way with gastro-intestinal derangement. The difficulty is that at times apparently exactly similar disturbances are unattended by fever. An easy claim is that ptomains from decomposition of intestinal contents cause them. It may be that a part of the cases are so caused, but as to many of them it is unproved and appears unlikely. The symptoms of constipation and diarrhea, of pain and swelling, are, so far as any clinician can tell, exactly the same a hundred times—an even many times in the same patient—when no fever occurs. It is easy to say that the fever must be due to some peculiar chemical or vital change not present in the other cases; and it is true that if abnormal metabolism within the digestive organs or elsewhere can cast into the circulation such substances as pepsin, peptones, albumose, fibrin ferment, or diastase, fever is produced. That such events do occur in these cases is largely conjectural.

13. We may fairly be in doubt to what degree nervous perturbation alone can cause fever. In a pus-poisoned patient, or one with an essential fever or tuberculosis, where there is even a trifling elevation of temperature, this is often made worse by mental excitement or by work. Can the excitement alone produce it when no poisoning exists? Probably not, since the greatest mental excitement—grief, fear, joy, anger—in a well person usually causes nothing of the sort. And in the cases where the fever is produced or raised by activity, is this due to the nervous excitement or to physical labor? A patient with tuberculosis or pus absorption, who keeps perfectly quiet in body and mind, may have a maximum temperature of perhaps 100 F. some time in the day; but a walk round the block or a business discussion of half an hour will carry it to 101 or 102. This is so well known that in sanatoria for consumption the rule is general that only patients wholly free from fever are permitted to exercise.

It seems impossible to deny that psycho-neuroses may disturb the heat-regulating machinery and produce positive fever. But the apparently fabulous fever reported of certain cases of hysteria is subject to honest doubt. Many physicians even deny that pure hysteria can cause fever. But the pronounced paralysis of motion and sensation, the spasms of several kinds, the hyperesthesias, and the erratic aberration of functions of almost every sort and degree, known the world-over as the result of hysteria, ought to make it easy to believe that the heat-centers may be involved as well. And if hysteria can affect them, then there is no limit to their possible degree of aberration, except the capacity of the tissues to produce and husband heat, and their tolerance of high temperature without coagulation.

14. There are numerous slight attacks of fever that seem inexplicable. They are short, and have few or no focal symptoms or signs, and no evidence of microbic poisoning save in the mere phenomenon of fever. That this fact is some evidence can not be denied. But if the reasoning is sound, then it is fair to assume that hitherto unknown microbes—or their life-history—capable of producing definite febrile action are yet to be discovered. Time was when rötheln was some erratic form of measles; now we know it to be a specific and probably microbic disease, differing wholly from the latter, and protecting its victim as measles does. Time was when myxedema was a freaky form of dropsy; now we have its perfect explanation—with what glory to modern pathology every one knows; and cretinism is analogous to it. Why should we not expect to find that other specific diseases have been occurring under our eyes and observation for years without our knowing it? And why should we, every time we are confronted with one of these inexplicable fevers, attempt to make it fit some of the grooves of known febrile disorders, as typhoid or malaria, or be unhappy if we can not? The effort to do this leads us often to hazard a diagnosis that, being false, we are forced to change in a few hours, or that we foolishly feel compelled to stick to throughout the case, to our discomfort and loss of self-respect. And we gain little, save with a peculiar portion of the public, when we load our uncertainties off upon some convenient scapegoat, the existence of which can neither be proved nor disproved. Formerly the scapegoat was malaria; now that malaria is so perfectly demonstrable, it is oftener grip—that can not be demonstrated; for the necessities of a scapegoat require that it shall be airy, indefinite, and incapable of proof.

During this very season numerous cases have occurred in many states, of suddenly oncoming fever, lasting two or three days, with slightly swollen, red pharynx, and no apparent follicular inflammation. The general malaise, weakness, and perhaps headache of the fever state have come and vanished in this brief period. Perhaps these cases were the true influenza; perhaps some other zymotic disease as yet unidentified.

The clinical significance of fever depends on other circumstances than the fever itself. High temperature, *per se*, is of small account. With a spot of sharp abdominal tenderness or rigidity of muscles, or with unconsciousness or spasm, coming on with fever, it may mean very much, as may a long-continued slight elevation of temperature without focal symptoms. This last leads us, especially in chronic cases with slight indisposition, to hunt long and faithfully for the cause. Clinically it is a valuable pointer.

The temptation among practitioners to treat the fever state is almost irresistible, but it should not ordinarily be treated. The wholesale medication so often used for this purpose is mischievous in the extreme.

If unconsciousness or convulsions attend high fever, showing brain involvement and perhaps a paralysis of some of the heat regulators, the temperature should be promptly reduced by baths, for through this act directly, or by some increased elimination it produces, the convulsions usually cease and consciousness returns. It is not true that fever of moderate degree must be brought down at once; fever often endures for a long time with little harm, as is shown in many cases of tuberculosis of the lungs, in which a slight daily elevation of temperature may persist for months with little impairment of the strength or general physical condition. Slight fevers may occur daily with no cachexia for a long time; the system becomes adjusted to it and the secreting organs are little disturbed.

A very high fever, or one that produces marked head discomfort, or great restlessness, may not improperly be reduced by means of coal-tar preparations or the ap[illegible]cation of water. But it is [illegible] that in [illegible] or other fevers the antip[illegible] [illegible] febrile temperature have creased the percentage of recoveries, and the habit of using them for this purpose has undoubtedly done much harm and very little good.

Probably the drug most extensively used for lowering fevers during the last thirty years—notwithstanding the free prescribing of the coal-tar preparations—is aconite; yet to this hour I am ignorant of any proof whatever that this drug can lower the temperature of fever, except by injuriously lowering the vitality of the patient. It may slow the heat and lessen nervous perturbation; but that is quite another thing.

We often find ourselves considering in the most serious manner as a grave thing the direct effect of a temperature of, say 102 F., and lasting for a few hours or for a day. And we have connived at the belief by the lay people that such a fever is dangerous. If placebos are needful for the *morale* of the patient, there is no objection to giving some innocuous thing ostensibly for the fever, but for doctors to regard it as necessary on other grounds is unscientific and poor practice. A free catharsis at the beginning of sudden fever often gives a sense of relief, probably by removing ptomains and other effete matter from the intestines, and in this or some other way removing congestion—or a sense of it—from the head. But except by removing ptomains there is small proof that it lowers the temperature; and evidence of this latter even is not of the best.

It is, of course, always in order to attempt to remove or destroy the causes of fever. Some of the more tangible ones, especially those of a surgical character, we may deal with effectively. We may evacuate effete matter from the alimentary canal and increase the toxicity of the urine, which it seems clear is one of the eliminative effects of the Brand treatment of typhoid, although many forms of treatment may help the system to free itself from the toxic influence.

The service of this sort which we can render is very sharply limited, and may be roughly indicated as follows:

1. Pus-pockets, suppurating surfaces, and cysts leaking into the connective tissue, and so reaching the general circulation, may sometimes be evacuated or removed.
2. Inflammation may be assuaged, cured, or waited for.
3. Ptomains in the alimentary canal may be evacuated by a cathartic if they do not directly bring on a remedial diarrhea.
4. Malarial plasmodia may be effectively dealt with; and we have, fortunately, one drug proved to have a positive action against these parasites.
5. The causes of the essential fevers, that obviously consist of specific microbes which run their course in definite periods, are usually destroyed by the conservative havoc wrought by the products of the microbes themselves. No drug is capable of destroying them, and, on the basis of present knowledge, it is idle to medicate by such means. But we are beginning to know that the destruction of these poisons is possible by artificial means acting like the physiologic forces. The success already attained in a few diseases, most notably diphtheria, is crucial proof of the possibilities in this direction, and is reason for the faith that we shall soon be able to deal with many diseases in the same way. This is the direction the efforts of every clinician ought to take, and we await the beck of the votaries of bacteriology and pathology.

It is hard to keep the practising part of the medical profession plumb, as it is the lay world. We easily drop into habits of prescribing for insignificant things, to the neglect of the few indications that make for the patient's better comfort and greater prospect of recovery—the two objects that alone justify the existence of doctors. We give aconite or other drugs for slight fever and to bring down the pulse; digitalis, because the pulse is weak at the wrist—even when the weakness is apparent and not real, but due to the muscular and nerve fibers of the vessel-walls; we give calomel to clean off the tongue; prescribe for dry and rough skin and for cold, clammy skin; and for temporary dark coloration of the urine—and all as though such things were consequential and not the necessary, harmless accompaniments of many sicknesses of all shades of severity. Worse, we often prescribe thus to the injury rather than the benefit of the patient, and by pursuing such methods hide from our own eyes the manner of reasoning that means growth and the measures that, beside being scientific, are genuinely useful for the health and longevity of the sick.

SURGERY OF THE TEAR-PASSAGES.*

J. G. HUIZINGA, M.D.
Professor of Ophthalmology, Chicago Post-Graduate Medical College.
CHICAGO.

What the physician of to-day wants more than anything else is a practical knowledge of the science and art of medicine as it is practiced by the leading men in the various departments into which the work is ordinarily divided. Theorists there always have been and always will be, and they undoubtedly serve a very useful purpose; but to the ordinary physician he is an unknown quantity. His logic and theoretical deductions may be interesting, even fascinating, but directly they are of extremely limited practical benefit, to either the physician or the patient.

With the exception of a very few, the members of this society are all general practitioners; or let me put it a little differently—they are general specialists, i. e., specialists in everything. In your every-day practice you are called upon to examine into and treat every form of sickness or accident that our bodies are heir to. Isolated as some of you are, you do not always have the time or opportunity of calling in the assistance and counsel of men who by special study and large experience have become experts in the different specialties. Allow me, therefore, to speak to you this afternoon about a group of diseases that every one of you must often have met, and without theorizing as to the how and why or whence, give a brief summary concerning their general diagnosis, care and treatment, together with a few hints as to the dangers to be avoided.

Among the most numerous and most important diseases that the oculist is called upon to treat are the diseases of the canal whose function it is to conduct the tears from the lachrymal lake into the nose. The epiphora which usually accompanies these diseases is so annoying and aggravating that persons suffering from it very soon seek medical advice. The tears, instead of finding their way through the passage ordained by Nature for them, are either prevented from entering the canal at all, or having entered, are hindered from passing through it. In either case it results in the tears flowing over the border of the lower lid on to the cheek. If this happens only occasionally, it will not seriously inconvenience the patient, but if it be continuous and, as is usual, aggravated by being out of doors, especially when it is windy, it will sooner or later result in considerable excoriation of the skin, besides the inconvenience of being obliged to constantly wipe away the tears. It must be remembered, however, that epiphora is not necessarily a symptom of obstructive disease of the tear-passages. It may be due to excessive irritability of certain endings of the trigeminus and occasionally it is found to precede Basedow's disease.

---

*Read before the Grand River Valley Medical Association, Aug. 15, 1899.

The canal being lined with mucous membrane, it may under certain conditions become subject to catarrhal inflammations. Sometimes this may be communicated to it from the nose; sometimes from a catarrhal conjunctivitis; sometimes it may be caused by the lodgment of a foreign body in the duct; but more often no definite cause can be assigned. Syphilis, a scrofulous diathesis, periostitis and erysipelas have all to be mentioned as possible causes. There is very little doubt that a certain per cent. of cases are the result of the extremely irritating qualities that tears occasionally possess. These changes, like those in the urine, are dependent upon the condition of the system as a whole, as it is influenced by this or that local trouble.

The characteristic results of a catarrhal inflammation —a swollen and congested mucous membrane, with an increase of the secretions, that readily decompose and become pyogenic—are sufficient to entirely close any part of the canal, and the formation of an abscess is only a question of time. Any suppuration, pus or infected sore anywhere near the organ of vision must always be considered as extremely dangerous. With the least abrasion of the cornea, and sometimes even without it, infection by this pus may produce abscesses and ulcers that often perforate and may ultimately terminate in panopthalmitis in the eye primarily affected, and possibly sympathetic opthalmia in its fellow. Or the orbital tissue may become affected, causing an orbital cellulitis that may terminate fatally.

Since such disastrous results may manifest themselves before the disease is checked, we need not be surprised at the heroic measures sometimes advocated for their cure or to restrict as much as possible any evil consequences.

Beginning at the palpebral end of the canal we often meet with a considerable narrowing or contraction of the punctum. It may be limited to either the upper or lower one, or may affect both at the same time. The normal diameter of these openings is .25 mm. for the upper and about .33 mm. for the lower. They act as the sphincters of the canal. The punctum is funnel-shaped and in close apposition to the eyeball. Immediately beyond the funnel-shaped opening the canaliculi expand considerably, so that a kind of valve is formed, which, while it encourages the entrance of the tears, to a certain extent retards their exit in this direction. According to Gerlach, a few unstriated muscle-fibers have been found surrounding it. The cause of any constriction at this point may be a long-continued congestion or inflammation of the palpebral conjunctiva. Often it closes entirely, as a result of a burn, as from a flame, from molten metal or from chemicals.

Because it is easy of access, the treatment of this condition is comparatively simple. If it is entirely closed, it will be necessary to use a narrow, sharp-pointed knife, like a broad von Graefe cataract knife, to open it. Unless a person has had considerable experience in treating such cases, it is not always an easy matter to find the opening into the canaliculus, even after it has been opened by this method. Our only guide is an exact knowledge of the position and direction of the canal. Sometimes it happens that a large proportion of the canal is closed. In this case it is necessary to make the opening a short distance beyond the punctum toward the median line, just within the upper or lower border of the lid, as the case may be, so that the opening in the lower lid may face upward and backward, and in the upper lid downward and backward. The tendency to heal and close again must be prevented by the daily use of a well-lubricated No. 6 probe, which must be introduced as far as the sac.

If there is simply a contraction without a complete closure of the punctum, dilatation, either rapid or slow, is usually sufficient. I prefer the rapid method. The upper as well as the lower punctum should be dilated, as the results of treating both are far more satisfactory than that of treating one alone. In fact, some cases absolutely demand it and would not get well without this form of treatment. The results, as a rule, are very gratifying and the patient is immediately relieved of a very annoying epiphora.

Narrowing or constriction of that part of the canal between the punctum and the sac is also quite common, especially at the junction of the upper and lower canaliculi and of the sac and the common duct. Its normal diameter is about .5 mm., and its length varies from 5 to 7 mm. It is surrounded by fibers of Horner's muscle, which assists the orbicularis palpebrarum in moving the lids, while at the same time it compresses the canaliculus and draws it toward the median line, thus shortening it with every effort toward closing the lids. The effect of this rhythmic compression and shortening is to force the contents of the canal into the sac. This results in a vacuum, which is immediately filled again by the tears from the lachrymal lake, entering through the funnel-shaped punctum. If any part of this canal is contracted it will prevent the tears from passing through it, and the regular compression and shortening of it will force the tears back again out of the punctum into the lachrymal lake. Thus the canaliculi are kept clean and washed out by the tears several times a minute, preventing stagnation, decomposition and abscess. For this reason it is exceedingly rare to meet with an abscess, or discharge of pus, whose origin is in the canaliculus. The only inconvenience that the patient complains of, therefore, is similar to that of closure or contraction of the punctum, viz., epiphora.

The treatment of this condition has been quite unsatisfactory in a large proportion of cases, and warrants us in trying to discover a better method. Dilatation is only of temporary benefit, and sooner or later the patient returns, no less to the disappointment of the physician than to himself. Often it seems as though the condition has been aggravated instead of relieved by it. Dr. Knapp, in writing on this subject in Norris and Oliver's "System of Ophthalmology," rather than subject the patient to the discomfort and uncertainty of dilatation, advises "patients with moderate epiphora to bear it without probing."

Slitting the canal and converting it into a groo[illegible]
as unscientific and crude as its results are unsatisfa[illegible]
and disappointing. Unless accompanied by suc[illegible]
cal and forcible dilatation of the nasal canal as [illegible]
by Theobold, it is a question in m[illegible]
does not seriously increase the diffi[illegible]
it into a groove we forever destroy [illegible]
function of the canaliculus, viz., th[illegible]
into the lachrymal sac. The tears [illegible]
lid to the nose because of the effe[illegible]
fact, the direction of the canalic[illegible]
and the tears, like the contents of [illegible]

along by the peristaltic action of the canal. Therefore, any method of treatment that interferes with this peristalsis or prevents it altogether should never be considered or advised so long as equally good results can be obtained by working in harmony with Nature. Theobold overcomes the bad effects of slitting the canaliculus by enlarging the entrance to the sac and the nasal canal to such an extent that a probe whose diameter is 4 mm. can easily be passed.

The objections to this are two-fold: 1. The amount of force required to pass such large probes is a "dangerous and reprehensible procedure" that not only severely lacerates the lining membrane, but, as its advocator himself acknowledges, often fractures the bony wall of the canal. I scarcely need do more than quote his own words: "Occasionally I have used the strength of both hands to pass these probes." 2. The other objection to it is still stronger, in that a large canal and a large opening in the lid allow the contents of the nose to be forced upward toward and on to the eye whenever the patient blows the nose, and thus constantly exposes the eye to all the dangers of infection from this source, which is little less than the danger of dacryocystitis, for which this operation is often performed.

In the treatment of strictures of the canaliculus two objects must be kept in view: 1. To obtain a canal of sufficiently large caliber to conduct the tears to the sac; 2, to preserve the normal function of the canal by not interfering with anything that would disturb the function of the organ and the forces that make this function possible. Simple dilatation of the constricted portion by means of ordinary probing alone is notoriously unsatisfactory, and the well-nigh universal opinion is that if a stricture, no matter where it be located, is to be permanently cured, it must be divided with the knife and its raw edges prevented from reuniting by repeated dilatation of the canal.

But how to cut without interfering with the physiologic function of the organ is the all-important question. After a careful study and considerable experience, I have adopted the following as my method of procedure: The punctum is dilated to such an extent that a knife made for this operation may be introduced with the least possible injury, for ordinarily it does not need to be cut. Having first ascertained the exact location of the stricture by means of probing, the knife is passed into the canal with the back of the blade firmly hugging the wall of the canaliculus toward the border of the lid, so as to injure the mucous membrane as little as possible. The sharp edge of the knife is directed downward in case of the lower, and upward in case of the upper, canaliculus, until it reaches the stricture, which is cut by a sawing movement. The knife is withdrawn just as carefully as it had previously been introduced. In the lower canaliculus the cut is made downward and in the upper it is made upward. In this way little or nothing is cut except the stricture, and the direction in which it is cut is such that it in nowise interferes with the proper physiologic function of the organ. It does not sever the fibers of Horner's muscle, which controls the peristaltic action of the canaliculus; neither is the canal converted into a groove, but it retains both the shape and the function of the organ.

The after-treatment consists of irrigations with boric-acid solutions and the regular use of a No. 8 Bowman probe as follows: Daily for the first week; every second day for the second week; every third day for the third week, and once a week during the three following weeks. I need scarcely mention that neither probing nor cutting should ever be attempted without first having taken the most perfect aseptic precautions possible.

Quite commonly stricture of the tear-passages is found at the junction of the lachrymal sac with the nasal canal. The canaliculus may be of normal shape and size and performing its functions perfectly, but the obstruction at the lower end of the sac prevents the tears from passing through into the nose. The retained secretions become stagnant, easily decompose, and on account of the well-nigh universal presence of bacteria and germs, readily become an infected and infectious mass. The irritating qualities of the fluid soon set up a congestion and inflammation of the lining membrane of the canaliculus, producing a swelling and consequent constriction of this narrow canal, which effectually prevents the exit of the infected fluid from the sac. The lining membrane of the sac becomes similarly affected, resulting in a purulent catarrh, which increases the contents of the sac, and a true abscess or dacryocystitis has developed. It manifests its presence by a fluctuating red tumor at the base of the root of the nose, with considerable edema and puffiness of the lids, so that frequently they can not be separated except by force. There will be epiphora, severe pain, headache, with perhaps slight chills and elevation of temperature. Its treatment is similar to abscess in any other part of the body. A large opening is made in the most dependent portion of the sac and the contents thoroughly evacuated, followed by flushing with boric-acid or bichlorid of mercury solutions. No attempt should be made at this time to open or dilate the strictures, as the swelling of the lining membrane is usually so great as to make this procedure impossible without the use of more force than is justifiable. The after-treatment is again similar to that of an abscess elsewhere, viz., thorough daily cleansing and dressing with antiseptic precautions until all discharge has ceased.

In addition to this, an attempt should be made to overcome the strictures and have the canal patent from end to end before allowing the opening to close entirely. If for any reason this is impossible, one of two methods may be followed: 1, the destruction of the lachrymal sac; and, 2, the establishment of a permanent fistula. Of these two, the former is to be preferred. It frequently happens that when the abscess has healed and the inflammation subsided, the stricture has also disappeared, proving that it consisted simply of a swollen mucous membrane.

On the third or fourth day after having opened the abscess, an attempt may be made to pass a small probe. If successful, it may be repeated every day by one of the next larger size. If unsuccessful, wait two or three days longer and try again, at which time there is usually no difficulty, unless complete closure of the canal has taken place. If a stricture exists it should not be cut or treated by any other method than simple dilatation until the abscess has completely healed and all danger of infection has passed.

If a complete stricture and an entire closing of the canal has taken place, we must first ascertain by means of a probe whether this obstruction is due to closure of the bony canal or whether it is simply the result of cicatricial contraction. If due to the first, the probe will encounter a firm, hard, irresistible barrier; if it is the result of the second, the contact of the probe with the obstruction will impart to the fingers a sensation not unlike that which would be conveyed to them if the probe were pressed against a piece of soft rubber. There is a certain amount of "give" and elasticity.

If after a careful examination it has been ascertained that the obstruction to the canal is of a bony nature, the treatment resolves itself into extirpation or complete destruction of the lachrymal sac, with or without excision of the lachrymal gland. Extirpation or destruction of the sac may be accomplished by one of three methods: either by a careful dissection, by means of the actual cautery, or by scraping and curettage. Preference should be given to these methods in the order in which they are mentioned, although the last is perhaps the easiest, and, if thoroughly done, is equally as successful as the others. The wound should be left open and allowed to fill in and heal by granulations, except when the first method is followed. In this, if the operation has been done under strict aseptic precautions, the wound may be closed immediately and healing by first intention is usually accomplished. The canaliculi should be slit and cauterized.

The operation for removal of the lachrymal glands seems to me to be gaining in popularity, and I can see no good reason why this gland should remain after destruction of the sac, since its presence is a source of considerable annoyance and inconvenience, and its absence is followed by no ill results. The secretions from the glands in the lid are sufficient to lubricate the cornea and keep the parts moist and comfortable.

If the obstruction is the result of a deposit of fibrous or cicatricial tissue, it is best treated by the same method as that used for stricture of the canaliculus, viz., cutting and dilatation with a No. 8 Bowman probe. Having passed the probe, it should remain *in situ* for about 20 or 30 minutes before it is withdrawn again.

The normal diameter of the nasal canal is about 3 mm.; but when we take into consideration that all the tears passing through this part of the canal must first pass through the canaliculi, whose normal diameter is only about .5 mm. each, then we must reach the conclusion that a canal whose narrowest part is not less than 1 mm. in diameter is plenty large to carry off all the tears that come to it. Any mode of treatment, therefore, which attempts to increase the diameter of the canal very much above this, especially if this is done at the risk of lacerating the tissues and fracturing the bones through which it passes, must seem absurd, to use no stronger term. Bowman's probe No. 8 is about 2 mm. in diameter, and any canal large enough to admit of the easy passage of this instrument from end to end is large enough to permit the tears to pass freely without producing epiphora.

Occasionally we meet with cases in which the formation and discharge of pus will continue even after the canal has been properly opened. In such cases I have had the best success by injecting a 2 to 5 per cent. solution of nitrate of silver, preceded and followed by a douche of a saturated solution of boric acid. When I say a "douche," I do not mean the injection of three or four syringefuls of the solution, but inserting a canula both into the upper and into the lower punctum, allow a pint of the fluid to flow through uninterruptedly by means of a fountain syringe or a siphon from a bottle. In desperate cases I order a use of the douche three times a day and the nitrate of silver every two to four days. Rarely is it necessary to use it every day. Thorough antiseptic irrigation for not less than half an hour at a time is of the greatest importance here as well as elsewhere.

It has never yet been my bad fortune to meet a case in which it was necessary to destroy or extirpate the sac in order to stop a discharge of pus. I do not deny that such cases are occasionally met with, and therefore the operation is a justifiable one, but it certainly should not be attempted except as a last resort and after every other method of treatment has been faithfully tried without success. "In resorting to such radical and heroic measures we must ever consider it as an evidence of our limited knowedge and inability to deal more properly with this sometimes so-complicated a condition," were the words of a noted surgeon in speaking of amputations, and they apply with equal force here.

Lastly, allow me to call attention to the necessity of being certain that no stricture exists at the nasal extremity of the canal. In many cases in which no stricture or narrowing of any part of the canal can be detected by the ordinary Bowman probe, there may nevertheless be a stricture at the inferior or nasal extremity which is not always reached by these probes. For this purpose it is necesary to have an extra long probe, which I believe was first suggested by Noyes. It is introduced just like a Bowman probe until it passes down about as far as these probes will go, when it is twisted around about a quarter of a circle, so that the point of it is directed toward the median line and pushed down about half an inch farther. In this way the entire canal is thoroughly dilated from end to end.

Having treated the tear-passages after the most approved fashion, we shall nevertheless be doomed to disappointment in a certain number of cases, unless the same careful attention and treatment are directed to the nasal mucous membrane. Time will not permit me to do more than simply call your attention to this important point.

100 State Street.

THE DIFFERENTIATION OF CHOREA AND THE DISORDERS SIMULATING IT.*

BY AUGUSTUS A. ESHNER, M.D.

Professor of Clinical Medicine in the Philadelphia Polyclinic; Physician to the Philadelphia Hospital; Assistant Physician to the Orthopedic Hospital and Infirmary for Nervous Diseases.

PHILADELPHIA.

In some of its aspects true chorea, the chorea of Sydenham, presents the features of an acute infectious disease. Among the phenomena suggestive of such an etiologic relationship are the mode of invasion, the seasonal prevalence, the self-limitation, the endocardial and articular complications, the liability to recurrence, and the postmortem findings in some cases. Further, optic neuritis has occasionally been observed.

The actual causation of chorea yet awaits final solution, but the belief is growing that the disease is dependent on irritative disturbance of the motor cells of the cerebral cortex, of either infectious or toxic origin. In the etiology, heredity, sometimes direct, at other times indirect, is a not unimportant factor. It is not uncommon to obtain a history of the disease in the parents or in other members of the family. Chorea occurs almost invariably in neurotic stock, so that, as with infectious diseases, the predisposition or the susceptibility, viz.: the fundamental condition of the nervous system, is an important etiologic influence. The competitions, the strains, the overwork, the anxiety, the successes, perhaps not less than the failures of school life, the profound changes that take place at puberty, and the emotional and other disturbances of pregnancy appear to be important contributing factors, lowering ph [illegible] resistance. Fright seems to be a less com [illegible] influence than is generally believed. Worms, eye-strain, peripheral irritation, and other so-called reflex influences probably play no part in the etiology of true chorea, as they may in that of the various forms of spasmodic tic. The apparent relations between chorea and rheumatism are yet obscure. The elaborate investigations of Morris J. Lewis have shown that both diseases prevail much at the same time, rheumatism first and chorea afterward, and that this corresponds with the greater prevalence of disease in general. In clinical experience, it is not rarely related that the choreic symptoms have developed in the sequence of those of rheumatism, while less commonly the rheumatic manifestations appear during the progress or in the train of chorea. The cause of neither disease has yet been established, and it can not therefore be determined whether it is identical or allied in each. Rheumatism also is looked on as an infectious disease, although its bacteriology has not been fully cleared up. A number of investigators have found different micro-organisms in the articular lesions and in the endocardial complications of the disease.

---

*Presented to the Section on [illegible] prudence, at the Fifty-first Annual Meeting [illegible] cal Association, held at Atlantic City, N. J.,

It appears likely that what is commonly designated acute rheumatism, clinically, really represents a group of diseases dependent on a number of different causative factors; and it should, therefore, for the present, be considered as a form of polyarthritis. Acute endocarditis can now safely be said to have a similar multiple, though bacterial, etiology. An observation made recently by Westphal, Wasserman, and Malkoff,[1] may throw some light on this obscure subject. From the blood, the brain, and the endocardial vegetations in a case of acute articular rheumatism, followed by chorea and complicated by endocarditis and nephritis, these investigators succeeded in isolating a micrococcus, susceptible of culture and capable of inducing polyarthritis in lower animals, with the appearance of the same micro-organism in the articular effusion. In commenting on this communication, Mircoli[2] reviews his earlier investigations on the same subject, as a result of which he concludes that both rheumatism and chorea are dependent on infection with pyogenic cocci, which do not, however, give rise to suppuration.

De Buck and Van de Weghe[3] have also reported a case, thought to illustrate the infectious nature of chorea and its relation to rheumatism. The patient was a girl in whom, in a third attack of acute articular rheumatism, complicated by endocarditis, symptoms both of chorea and of profound nervous disturbance appeared.

At a recent meeting of the Pathological Society of London, Abraham demonstrated sections from a fatal case of chorea of pregnancy, showing inflammatory and degenerative changes in the cerebral cortex, suggestive of toxic alterations in the blood.

Cases in which cerebral lesions, such as hemorrhage or embolism, have been found were probably not instances of true chorea, but rather examples of choreiform movement.

Chorea often sets in abruptly; at times, with maximum, and at other times with progressive, intensity. Chills, convulsions, nausea, vomiting, or diarrhea, do not occur; and the temperature is not elevated, as a rule, unless in consequence of the violence of the movements. Hyperpyrexia, when present, has been attributed to rheumatism. The period of greatest prevalence of the disease appears to be the spring of the year. Under treatment with arsenic, which seems to exert an almost specific influence, its duration is, on the average, from six to eight weeks; although there is reason to believe that under favorable hygienic and dietetic conditions, without the use of drugs, the disease would terminate spontaneously in a not much longer period. Endocarditis is not rarely observed as a complication and valvular disease of the heart as a sequel or sometimes even as an antecedent condition. Arthritis is occasionally an antecedent condition, sometimes contemporary and rarely a sequel.

The movements of chorea are peculiar and distinctive. They may begin in one and extend to the other member on the same side, and remain confined to this side; or they may extend successively also to members of the opposite side. Occasionally they are present only in the lower or the upper extremities, but most often one side is more profoundly affected than the other, while sometimes the movements are general from the outset. The face is, as a rule, involved, and speech is often affected, the tongue being described as thick. The movements are irregular, jerky, disorderly, inco-ordinate, purposeless, sometimes violent and incessant. They are beyond voluntary control, being occasionally aggravated by efforts in this direction, as they are also by excitement, *emotional disturbance and observation.* As Weir Mitchell and Rhein have shown, the movements are sometimes increased, sometimes restrained, and sometimes unaffected by voluntary movement, and cease during sleep, although they may prevent the patient from falling asleep. The knee-jerks are sometimes deficient and often capricious and irregular. The temper is generally irritable. The motor inco-ordination is often attended with muscular weakness and this may be so pronounced as to simulate hemiplegia or paraplegia. Mental symptoms are generally not marked, but the patient often presents a peculiar foolish or fatuous appearance, with lack of power in concentrating the attention, though intelligence is preserved.

The disease designated habit-chorea, habit-spasm, or preferably spasmodic tic, does not result from the same causative factors as chorea, to which it bears no closer relation than that both are motor neuroses attended with involuntary movement. It, likewise, thrives best on neurotic soil, but it bears no relation to rheumatism, it presents no features of an infectious disease, it is unattended with endocardial complications, the character of the movements is different, and, most important of all, its duration is uncertain or indefinite, and it may or may not improve under treatment with arsenic. Of its intimate etiology little is known, but it seems to be the disorder that has been mistaken for chorea, attributed to reflex influences. Peripheral irritation, such as errors of refraction, insufficiency of the ocular muscles, conjunctivitis, nasal or oral disease, carious teeth, a tight prepuce, a painful cicatrix, intestinal parasites, or any local irritation may be the exciting factor. The disease may also arise as a result of imitation or habitual performance of a given act. The movements are different from those of chorea, being often co-ordinated, purposive and repetitive. They may disappear from one situation and reappear in another. They do not interfere with voluntary movement and are more distinctly intermittent. Facial movements are perhaps most common. Grimaces, blinking of the eyes, distention of the nares, pursing of the lips, elevation of the eyebrows, shrugging of one or both shoulders, are also common. An arm may be jerked, a foot kicked, a halting movement or some other definite, usually simple act performed; sometimes vocal utterances are associated. The movements may, in one form or other, persist for years, usually with remissions, occasionally with intermissions. They cease during sleep, and can be restrained temporarily by an effort of the will. They differ from the movements of chorea in their distribution, their character, their persistence, and the absence of seasonal relation.

[3] Belgique Médicale, Dec. 7, 1899.

Painless facial spasm, or mimic spasm, may be considered as a variety of convulsive tic, and is to be differentiated from chorea by its localization, involving one or several muscles on one or both sides of the face; its association with disease or paralysis of the facial nerve, or the facial cortical center, and its occurrence in adults, rather than in children. The spasm may be clonic, or tonic, and is relieved by rest and increased by emotion and activity. The disorder is irregular in course, and usually long in duration.

The athetoid movements that attend certain lesions of the brain sometimes closely simulate those of chorea; but so far as their peculiarity can be expressed by words, they are rather vermicular or serpentine, as compared with those of chorea, and less jerky, and rather progressive than abrupt. They, too, are inco-ordinate and involuntary, but they are usually confined to the same member or members; they persist indefinitely, and are but little susceptible to therapeutic intervention; and they are, as a rule, although not always, associated with palsy and other spastic phenomena, and often with evidences of mental deficiency. They are excited or intensified by voluntary movement, and sometimes in association with other movements, and by excitement.

So-called chronic or senile chorea, the disorder described by Huntington, is dependent on degenerative changes in the cerebral cortex, and occurs only in adult or late life. While the movements are much like those of chorea, they do not yield to treatment, and with them mental aberration becomes associated. The onset of the disease is gradual, the movements are less abrupt and jerky than those of chorea, the gait may be staggering, and other members or ancestors in the family may have been attacked.

Hysteria may be attended with various disorders of movement, some of which may closely simulate chorea. These, however, are usually more abrupt in onset, more rapid, more shock-like, and more rhythmic than those of chorea, and they are, as a rule, associated with other hysterical stigmata. It should, however, not be forgotten that a hysterical patient may also be choreic or vice versa. So-called chorea major is a manifestation of hysteria, as is probably also so-called electric chorea. The fatal disorder known as Dubini's disease, or electric chorea, is probably an infectious disorder, and is attended with muscular weakness and atrophy.

Torticollis, or spasmodic wry-neck, in a child may simulate chorea. Here the movement, however, is confined to a few muscles, and is always of the same character. It may be tonic as well as clonic.

The nodding, or rotatory spasm, observed in rachitic children, differs from chorea in its limitation to the head, in the exceedingly early period of life at which it occurs, in its association with other symptoms of rickets, and its disappearance with improvement in the nutritional state. The character of the movements is sufficiently described by the name.

Saltatoric spasm, jumpers, myriachit and latah, as well as other forms of myoclonus, are rare diseases, whose discrimination from chorea is rarely necessary.

224 South Sixteenth Street.

RECENT PROGRESS IN THE ROENTGEN-RAY METHODS OF DIAGNOSIS.*

BY CHARLES LESTER LEONARD, A.M., M.D.

PHILADELPHIA.

The operative technique of modern surgery is the result of a process of evolution which is based upon the more accurate knowledge of the sources of infection and the formation of pus. The employment of asepsis and antisepsis, as a consequence, has had the result of decreasing the mortality in a field of operating that is ever widening, and narrowing the horizon of the inoperable and hopeless.

The value of operative intervention is limited only by the inability to recognize the pathologic process at a sufficiently early period. It is impossible to restore to perfect functional activity organs seriously injured by disease. Marked progress can not be looked for in operative technique. A high average result can be obtained by an ever-increasing number of operators.

The innocuousness of surgical operations is leading to an increased employment of purely exploratory operations and to operations that are not based upon a clear diagnosis of the pathologic process that is present.

Progress in surgery can be expected when these methods are set aside and more accurate methods of surgical diagnosis are substituted. An early, accurate diagnosis is now the *sine qua non* of a successful restoration of function. Progress in surgery will keep pace with the development of accurate methods of diagnosis and be proportionate to their advance.

The new method of physical diagnosis which is the subject of this paper is but one line in which surgical diagnosis is progressing. Physiology, pathology, bacteriology, and chemistry are all aiding. The phonendoscope has increased the powers of perception and differentiation in auscultation and percussion. Direct cystoscopy and the catheterization of the ureters have produced results in the clinical examination of the female that are approximated by analogous methods in the male. All these methods possess an increased amount of precision, which, like the clinical thermometer, is the result of a basis on purely physical laws.

The Roentgen-ray method of diagnosis owes its accuracy to these elements of physical precision. The physical phenomenon upon which this method is based is the production of a form of radiant energy, which emanates from a vacuum tube when a high potential current of electricity is passed through it. The best scientific opinion holds that this form of radiant energy is a light-wave which lies far beyond the ultraviolet in the spectrum. It is sufficient for its use to know it obeys the laws of rectilinear rays and can not be reflected or refracted. Its peculiar physical properties that make it valuable in physical diagnosis are the power to penetrate in varying degrees, substances that were formerly considered opaque, and to register the amount of penetration on the fluorescent screen or the photographic plate.

The pictures or skiagraphs produced are shadows, the varying densities of which correspond to structures, each of which has a relatively constant resistance to the penetration of the Roentgen discharge. The more opaque substances are represented by denser shadows, since they absorb or disperse the most rays; the less opaque permit more rays to pass, while the least opaque or complete penetration are represented by absence of shadow.

---

*Read by invitation at the annual meeting of the Medico-Chirurgical Faculty of Maryland, Baltimore, April 24, 1900.

Although all substances constantly maintain their relative opacity, their shadowy representations vary with the shortness or length of the exposure and the quality of the Roentgen discharge. The discovery of the varying effects produced by rays discharged from the Roentgen tube during different states of the vacuum led to their careful study. Professor Roentgen has termed these states "soft," "medium" and "hard." Various attempts have been made to secure accurate fluorometric measurements, but with only partial success. A physical measurement that is fairly constant and directly applicable to any tube while in action is the measure of the length of the equivalent spark-gap in air in a parallel circuit. This measure is very practical, as by it the self-regulating tube can be adjusted at any time to produce any desired quality of Roentgen discharge.

By this standard the "soft" tube will have an equivalent resistance less than 1½ inches of spark in air. The resulting negative will show differential shadows of the less dense structures, while the bones will be but slightly penetrated. The "medium" tube has an equivalent resistance of from 1½ to 2½ inches. It produces negatives of strong contrast, with some penetration of the bones. The "hard" tube has a resistance above 2½ inches and produces a flat negative, without contrast, and is chiefly of value in detecting foreign bodies more opaque than bone.

The volume of Roentgen discharge is an important factor and is dependent upon the volume of the secondary discharge that energizes the tube. It was a deficiency in volume that formerly made it impossible to penetrate the denser portions of the body with rays that would produce tissue differentiation. This is the defect of the static-machine energy.

The recognition of these varying qualities of Roentgen-rays and the adaptation of them to the particular fields where they are most useful is an essential of technique and marks the source of the latest development in the adaptation of this method of surgical diagnosis.

The improvement in the construction of apparatus, and the development of the self-regulation tube are responsible for the flexibility and adaptability which the rays now possess. With the self-regulating tube, it is possible to obtain and maintain any desired quality of Roentgen-rays for any length of time. The power to maintain the tube at a low vacuum for any desired length of time is responsible for the progress which has been made in tissue-differentation. This is in turn responsible for much of the advance made in surgical diagnosis and will be the father of future advances.

THE X-RAY AN AID IN THE STUDY OF ANATOMY.

Before discussing the adaptation of this method to diagnosis, it is well to point to its possibilities as a method in anatomical studies. The injection of opaque fluids into the veins, arteries, sinuses, or cavities of the body renders their relation to each other and to the bones visible. The relation of the bones in different positions of the joints forms the basis of a comparison with pathologic condtions.

DETECTION AND LOCALIZATION OF FOREIGN BODIES.

A most useful as well as most obvious application of this method was found in the detection and localization of foreign bodies. A great advance has been made in their localization. The early crude methods are replaced by simple processes which are remarkable for the mathematical accuracy of their results. The surgeon's knife is directed by these calculations directly to the most minute fragments. These localizations are very valuable, especially, of foreign bodies of the eye. In all cases the operation must follow immediately upon the localization, especially in the case of the eye, since the electromagnet is unable to overcome the resistance of the dense adhesions that rapidly surround a minute fragment. In these cases the negative value is almost as great as the positive. It prevents meddlesome interference where no foreign body is present, or when it lies either in a position from which no further trouble can be expected, or where the surrounding vital structures make it unsafe to remove it.

DIAGNOSIS AND TREATMENT OF FRACTURES.

The value of this method in recognizing and directing the appropriate treatment for individual cases of fracture is not fully realized by the profession at large. It is, however, fully recognized by many leading surgeons who constantly employ it in their diagnosis and setting of fractures. They control their results in setting by its use, and refrain from much interference with the dressings which would otherwise be necessary.

The later developments in its employment and the increased definition in the skiagraph, enable the most minute fractures to be detected. The cancellated structures of the bones can be distinctly shown, so that linear fractures without displacement, or impacted fractures can be shown with distinctness. The rapid swelling that follows fractures involving the joints adds greatly to the difficulty in detecting the fracture. Crepitus, that crude sign of fracture, is wanting on account of the exudate into the line of fracture.

The progress in surgery which this method has made possible is very great. The pain and agony of fracture-examination can be entirely avoided. More definite and absolute knowledge can be obtained in a scientific manner, without causing the least discomfort. The time has arrived when the manipulation of a limb suspected of fracture should be considered meddlesome surgery. It causes the patient pain that is unnecessary, and inflicts serious injury on tissues already devitalized by traumatism, that may greatly retard or even prevent recovery. The knowledge gained by this method of diagnosis should have as important an effect upon the treatment of fractures as upon their diagnosis. It is a simple matter to show that many forms of apparatus now employed to produce immobility are failures. The individual fracture needs its own peculiar and appropriate dressing. The skiagraph has shown how great the variation in type is from the classic, empirical and schematic descriptions of the text-books. It is necessary to study carefully the mechanical elements involved in each fracture. The transverse, oblique, spiral and all other fractures each demand their appropriate treatment. The determination of the exact line of fracture directs attention to the mechanical difficulties that will be met with in reducing the fragments to their proper position and in retaining them there. It shows where the danger from exuberant callus is to be guarded against or the blocking of the joint by the protrusion of a fragment.

Many simple fractures have been shown to be more dangerous to function than the compound fracture. The shape of the fragment can be seen in a compound fracture and the small fragments removed, while fixation methods can be employed if essential to repair. They should be employed in many cases of simple fracture. The amount of displacement, the involvement of joint surfaces, and the extensive rupture of ligaments can be inferred from the altered relations of the bones that enter into the joint. The rarity of intercapsular fractures has been found to be due to the failure to detect them; this is also true of many other rare fractures. "Bad sprains" have frequently been shown to be unrecognized fractures.

The progress made in this form of diagnosis has increased the power to recognize fractures until it is possible to absolutely exclude fractures of the limbs. Fractures of the skull or of the vertebræ can be recognized only in particularly favorable cases and can not yet be excluded. It has been considered the duty of the surgeon to treat all cases of suspected fracture as if the fracture existed, unless it could be absolutely excluded. This practice undoubtedly resulted in procuring the greatest good for the majority of patients; and yet many of them have been deprived of much valuable time, and have been subjected to unnecessary confinement in bed and to needless expense, where no fracture really existed. Since, as has been mentioned, the accuracy of the skiagraphic method of examination is now so great that fracture can be detected, or absolutely excluded in all suspected cases of fracture of the limbs, there is no longer any ground on which such a course of treatment can be justified. Absolute knowledge can be obtained in the majority of cases on which a more rational line of treatment can be based. Much has been written and said regarding the inaccuracies and fallacies of the Roentgen rays. These so-called fallacies are not faults in the Roentgen-ray method of diagnosis, but errors in the technique of its application. Such errors in technique are but human and the result of the faulty employment of this mechanical method. It should not be judged by the errors introduced by the poor technique of the observer. If operators would study to find out and correct these errors, they would confer a greater benefit than they do by charging their ignorance to the account of a method they do not understand. Another valuable use of the skiagraph in connection with fractures is the confirmation of the reduction, and the assurance, that the skiagraph can give, that the dressings are sufficient to retain the fragments in proper position. Such a skiagraph is also very valuable evidence in demonstrating the fact that the fracture was properly reduced and an appropriate dressing applied.

CORRECTION OF DEFORMITIES DUE TO NON-UNION.

The correction of the deformities resulting from vicious union is greatly facilitated by this method of study and the knowledge obtained by it aids the operator in correcting the condition which was responsible for the trouble. In cases of suspected non-union it is not always possible to establish the fact, especially at an early period, as the time when callus becomes opaque varies. Six months is probably a safe limit. The only method, however, by which non-union can be proved is by the production of a change in the relation of the fragments that can be detected by the skiagraph.

Asymmetry and functional disability do not always go together. Many old fractures that are not symmetrical when studied by the skiagraph have yet produced no permanent disability. On the other hand perfect osseous symmetry may be present, and yet the injury have produced such serious lesions of the soft tissues, which can not be recognized by the skiagraph, that a permanent and lasting disability results.

It can be readily inferred from this that skiagraphs can not form any basis upon which damages can be assessed in suits at law. They have, however, a distinct value, the bearing of which upon the facts in the case is gradually being determined. Although the question requires deep study and consideration, it is, perhaps, safe to say that they have been admitted as evidence and as such are capable of determining whether a fracture has taken place or not, provided the examination is made within a reasonable time after the injury; what the line of fracture was, and what its bearing upon the difficulties of treatment would be. In all cases in which skiagraphs are admitted as evidence, expert testimony should be called by both sides and the privilege demanded and used of examining the patient by this method. Skiagraphs under these conditions will demonstrate the absolute facts. Without expert explanation they are liable, by their erroneous visual impressions, to mislead the jurors. Skiagraphs taken with the fixation dressings in place are a safeguard to the practitioner and evidence that the result desired has been accomplished. They should never be given to patients except by the surgeon in charge or with his consent, as misinterpretations may result in serious trouble.

IMPORTANCE OF X-RAY TO ORTHOPEDICS.

Orthopedic surgery has already been greatly benefited by this new method. The predetermination of the exact osseous deformity facilitates treatment or points out the exact operative intervention that is demanded. The various pathologic conditions that simulate each other in outward appearances are readily differentiated by this method. This is particularly true of diseases of the hip. In spinal disease the extent of the deformity, amount of rotation or involvement of the bones by tubercular disease, is readily determined. Metatarsalgia was accurately described by Morton years ago; the proof afforded by the skiagraph and the determination of the exact point for operation are invaluable additions. The result of osteoplastic operation and the efficiency of fixation dressings can be studied, and valuable lessons learned.

The study of the malformations and regenerative processes found in the bones is not the only value of this method. The fact, that in the majority of pathologic processes involving osseous tissues there is always an absorption or an increase in the amount of the bone salts, makes the study of these processes possible by this method, since it is to these salts that the bones owe their opacity. Hypertrophy or atrophy can be readily detected and confined to a more limited area. The shape and size of exostoses and osteomata can be seen, and the needed intervention predetermined.

DIAGNOSIS OF ANEURYSMS.

In November of 1896, Dr. Pepper, in discussing the value of "Skiagraphy in the Diagnosis of Aortic Aneurysms," in a paper read before the Pan-American Medical Association in Mexico, said: "In many cases the new agent serves only to confirm a diagnosis which has already been established with great confidence by auscultation and percussion. Even in these cases we may hope for greater precision as to location and size and form. In other cases, however, an intrathoracic aneurysm of such small size, or so situated as to cause but few symptoms, and not susceptible of diagnosis by ordinary methods, may be demonstrated by the X-rays. Lastly there are cases where symptoms strongly suggestive of aneurysm are present, and the gravest anxiety must be entertained, since clear diagnosis by exclusion may be impossible, and yet the employment of the X-rays may be of positive value as failing to reveal an increase in the shaded form of the heart and aorta."

The progress which has been made since that time has more than realized the expectations expressed. The size and position of aneurysms that lie too deep to be detected with certainty by other methods can be shown by the skiagraph. Their pathognomonic expansile pulsation can be seen upon the fluoroscopic screen, and the increase or decrease in their motion noted as indicated by a thickening of their walls and as a progress toward increase or recovery.

VALUE AND LIMITATIONS OF THE FLUOROSCOPE.

It will be of service to stop for a moment and consider the value and limitations of these fluoroscopic examinations. What value ought to be placed on the assertion based on these observations? It is but a transient image that affects the eye of the observer. It can not be mechanically registered or reproduced. It is, therefore, impossible to compare them with any fixed standard or normal, or with any other case, or any other observer's impressions except through the senses of the individual. How inaccurate these observations must be! The normal has physiologic variations that are absolutely unknown in this relation. In appearance they may approximate so closely to the pathologic in its incipiency as to make it impossible to differentiate between them. These fluoroscopic images can never be more than the personal observations of the individual; as such they may approach in accuracy the results obtained by other methods of diagnosis, but they lack the element of mechanical accuracy based on physical laws, that would give them a greater value. As the opinion of the individual observer they should receive only that amount of credence which any similar personal opinion would receive, and must depend entirely upon the acuity of his perceptions for their value. They are chiefly valuable in detecting abnormal motion and in confirming observations made by other methods. Gross variations are readily detected. It is not possible to detect the lesser, incipient pathologic variations from the physiologic normal or one pathologic condition from another.

A great deal has already been claimed for the fluoroscopic methods in the diagnosis of incipient tuberculosis. As confirmations of other methods they may have some value. They lack a purely mechanical process of production and a known fixed normal to which they can be referred. They undoubtedly aid the observer in confirming other impressions; but they are simply impressions and can not differentiate between the incipient pathologic and physiologic variations; they can only have a value as personal opinions secured by employing the sense of sight in a new method; since they are limited by the observer's acuity of perception, they can have no other value.

SKIAGRAPH MUST DISTINGUISH BETWEEN SOFT TISSUES OF DIFFERENT DENSITIES.

Further developments, and results that have the element of mechanical accuracy, can be obtained only by an improvement in this power to differentiate, by the skiagraph, between the less dense tissues. Some progress has already been made in this direction. Areas of infiltration and cavities with their surrounding wall of tubercular infiltrates can be shown in the skiagraph, while the progress of the disease can be recorded in a series of skiagraphs. They are also valuable in mechanically confirming the details of a diagnosis which has been made by the other methods.

The employment of this method in detecting consolidation of the apices and the incipient stage of tuberculosis would render the greatest service. It is, however, impossible, even where the skiagraph detects the increased density due to consolidation, to prove that this opacity is due to a tubercular deposit, or that it is even pathologic, except by employing, in conjunction, other methods that are now in vogue.

SURGERY OF THE KIDNEY.

Within the past twenty years the surgery of the kidney has been developed. The untiring efforts of clinicians and operators have already done much in systematizing the symptomatology, and in determining the various pathologic processes that involve these organs. More, however, must be accomplished if the early recognition and differentiation of these conditions is to be sufficiently accurate to render operative intervention of the greatest service. The similarity of the symptoms is so great that they may readily be confused and the differential diagnosis be impossible. The difficulty is increased when one or another symptom is masked or wanting. Frequently the symptoms become so severe and the condition of the patient so serious that operative intervention is indicated before a definite diagnosis has been reached. Here, where surgical diagnosis is often so deficient, this method has overcome the difficulties of diagnosis, and through it an absolute addition to knowledge can be secured. The absolute negative as well as the positive diagnosis of renal calculus can be made by this method, even when there are so few signs and symptoms that only a suspicion of its presence suggests the examination. Thus expectant or non-operative treatment is rendered rational where it otherwise would have been hazardous.

RENAL CALCULI.

Calculous nephritis is a pathologic condition in which delay in forming the diagnosis is most serious in its results. The mortality from early operation when the calculus is small, is but 2 or 3 per cent.; delay rapidly increases the danger until in the presence of suppuration it reaches 25 per cent. or more. Recovery after early operation practically restores the kidney to its primary and complete functional activity. The longer the pathologic process is permitted to remain undisturbed, the greater is the injury and functional loss; while if it continues undetected the entire kidney may be destroyed, or atrophy may set in and result in complete functional disability.

Clinical experience and post-mortem findings have shown that the danger from quiescent and unsuspected calculi is very great. Even where the symptoms unmistakably point to calculus and operation is indicated, there is always grave danger that the other kidney may be involved in the calculous disease. The formation of calculi depends upon some systemic cause, so that the possibility of the presence of a calculus in the other kidney should never be forgotten. Many operators even advocate double exploratory nephrotomy to guard against operation on the wrong kidney or when both kidneys are the seat of calculous disease. This is one of the problems that this method has solved. Quiescent or unsuspected calculi, that have either made their presence felt by one attack, where the symptoms have entirely subsided, or have never given rise to sufficient symptoms to cause more than a suspicion of their presence are a great danger, since their presence threatens, sometimes the integrity of one kidney, sometimes the life of the patient. These calculi, that are generally minute, are dangerous, because they may became impacted in the ureter and thus give rise to a partial unilateral anuria, or, if the other kidney has been prevously destroyed, to complete anuria and the death of the patient.

Post-mortem examinations have frequently demonstrated that the total destruction of one kidney has been accomplished by this process, or the suppuration resulting from the presence of one or more calculi, and that death has ensued when a calculus has formed in the other kidney and blocked its ureter. The process by which a kidney is thus destroyed is so insidious that destruction may simulate recovery. This pressure of the urine, dammed up in the ureter, soon equalizes the intranephritic blood-pressure; the kidney ceases to act, and loss of function is followed by atrophy and degeneration, until nothing may remain but a mass of fibrous tissue. The symptoms that ushered in the anuria subside completely and the patient has apparently recovered from the attack. There is in fact, such a complete simulation of recovery that undoubtedly many of the "cures" attributed to internal medication would be shown by post-mortem examination to have been in reality the cessation of symptoms because the kidney has been destroyed; while many other cases never had a calculus.

The patient who has suffered from an attack of renal colic, or in whom symptoms are present that point to the possibility of a calculus, can never be said to be out of danger until the absence or exact location of the calculus has been established. So long as the calculus remains in the patient's kidney or ureter, there is always danger of partial or complete anuria. If the calculus exists, its presence should be detected, and it should be immediately removed; if there be no calculus, the patient should have that assurance, as a basis for the rational treatment of the condition that produced his symptoms. Quiescent and unsuspected calculi are not the only difficulties met with in forming a diagnosis of renal calculus. Other pathologic processes, either within or outside of the kidney, simulate it so closely that their symptoms differ only in some minute particulars or degree, and are often so nearly alike as to render a differential diagnosis impossible by ordinary methods. The classic symptoms are seldom found and are nearly always wanting in the incipiency of the disease, when the very smallness of the calculus makes it most dangerous and when operation is most favorable and the loss of function the slightest.

The conditions that simulate calculous nephritis and render the differential diagnosis difficult are inflammations of the kidney, varying in degree from a simple hemorrhagic pyelitis to complete destruction of the kidney by a suppurative process. The formation of a benign or malignant tumor in the kidney may produce symptoms that are the counterpart of the early calculous pyelitis and can not be distinguished from it in the earlier stages, or until the tumor has reached a palpable size. Tubercular disease of the kidney is most difficult to differentiate. The similarity of symptoms is very close, and when it is impossible to detect the tubercle bacillus in the urine, the differentiation is often impossible.

The excessive secretion of oxalic or uric acid may give rise to a symptom-complex that is difficult to separate from true calculous disease. *In fact it is probable that* these conditions are often the prodromal stage of calculous formation and the negative diagnosis established in such cases can not guarantee that the patient will not form and pass calculi or gravel at a subsequent period, unless the systemic condition responsible for these excessive excretions is corrected. Ureteritis with or without the formation of a stricture may be very difficult to differentiate from calculous disease.

Other conditions than those that are purely intranephritic and yet that involve the kidney may produce a resemblance in their symptomatology that is very close to that of calculus. Abnormal motion, either in the form of the floating kidney with a wide excursion from the normal position, or the movable kidney with a lesser, yet pathologic, displacement, may give rise to twists or sharp angles in the ureter or the renal artery and veins that will produce alterations in the flow of the blood or in the escape of the urine, thus altering the intranephric blood-pressure or the intrapelvic urinary pressure. These alterations may produce periodic congestions or an intermittent hydronephrosis. They are acute in type and have such crises of pain and are often attended by hemorrhage to such an extent as to make it impossible to exclude calculus. The continuance of these conditions or of an acute hydronephrosis may in time result in pathologic malformations, which have been variously described as valvular folds or twists of the ureter. Perirenal abscesses and inflammations or cicatricial adhesions and contractions may also play their part.

Besides these numerous conditions within and outside the kidney, other diseases in distant or neighboring organs may be readily confounded with calculous disease of the kidney. The ovaries, the appendix, and the gall-bladder are all the seats of pathologic processes producing symptoms that may be readily referred to the kidney. Ulcerations or malignant disease in the stomach, intestines, or other parts of the genito-urinary tract, may produce crises of pain that resemble very closely nephritic colic, since the pain is often referred to the kidney. Disease of the lumbar spine in its incipiency is frequently accompanied by pain that is lancinating in type, and may be mistaken for nephritic pain occasioned by a calculus.

This résumé of the conditions in which the symptomatology is confused with that of calculus, shows how readily mistakes may arise, and how impossible it is to prevent them by the ordinary means of diagnosis at present at command. The list of operations performed for stone in which none were found would be very large if all were reported. Mr. Henry Morris, who is probably the greatest authority on renal calculi, has reported forty-four cases in which he operated for stone and found none. The patients in the majority of these cases were benefited, since the pathologic process present was determined, and frequently complete recovery ensued. Many other operators of the highest diagnostic ability have made similar mistakes. In many of these cases exploratory nephrotomy was indicated. Such operations are indicated, even where calculus has been excluded, whenever the symptoms point to a process the persistence of which would endanger the function or vitality of the kidney; they are, however, unjustifiable for suspected calculus, since their absence or presence can be absolutely determined by the Roentgen-ray examination. Surgical opinion has already reached the point where it condemns the incision of the kidney during an exploratory operation, unless some macroscopic lesion demands it, or a calculus has been shown to be present by the skiagraph.

Two cases have come within the author's personal experience in which the Roentgen-ray diagnosis was the only indication for incising the [illegible]. In [illegible] ase th [illegible] calculus was found and the [illegible] serious injury had been done t[illegible] of these cases the incision of t[illegible] an unjustifiable procedure if the presence of a calculus had not been predetermined, as there were no macroscopic indications of its presenuce.

These various simulations of calculous renal disease, and the benefits secured by the employment of the Roentgen-ray method of diagnosis have been illustrated by the series of seventy-four cases in which an absolute negative or positive diagnosis has been established.

HYDRONEPHROSIS.

The benefits derived from this method of diagnosis are not confined to the detection or exclusion of calculi. In three cases a hydronephrotic condition was shown; in one instance accompanied by three calculi that were subsequently removed; in a second there was a pure pyonephrosis where the negative calculus diagnosis was subsequently proved by operation. The third case is of particular interest, as it illustrates the possibilities of this method and what may be expected from further developments. Attacks that simulated a mild form of appendicitis had persisted for about three months, recurring at intervals with an exacerbation of the symptoms. The presence of a slight amount of blood in the urine after these attacks was the only symptom or sign that pointed to renal disease. It suggested calculus and the patient was referred for a Roentgen examination. The skiagraph showed the absence of calculi and in addition an opacity, greater than that of the rest of the kidney which corresponded in form with the pelvis. The outline of the pelvis was not visible in the other kidney shadow, showing that some pathologic condition must have been present to produce the contrast. The clinical history made it highly probable that this shadow was due to the distension of the pelvis by bloody urine, forming a condition of acute hydronephrosis. The subsequent history justified this conclusion. Another case similar in character in which a hydronephrosis was detected was shown by the catheterization of the ureter to be correct, as a large amount of pus was withdrawn.

In another case which exhibited no renal symptoms and in which a true cystitis had been excluded, the skiagraph showed a minute calculus in the ureter just outside the bladder. Its position was beautifully demonstrated by the shadow of the bladder wall. In another pelvic examination the shadow of the enlarged prostate was distinctly visible. No detail was, however, added to the diagnosis that had been made by other means, except that calculi were excluded.

The production of such detail and differentiation in soft tissue shadows points out the way for further advance in diagnosis. The value of the detection of abscess formation, as the result of tubercular disease in the kidney will be very great. A nephrectomy will, if the diagnosis can be made sufficiently early, completely eradicate the disease.

THE EXACT LOCALIZATION OF THE CALCULUS.

The exact localization of the calculus is one of the great advantages of this method. Not only is the operation rendered complete by the definite determination of the number of the calculi, and the question of the involvement of the other kidney decided, but the exact location also limits the operative intervention to a particular portion of the kidney. Thus a calculus weighing 42 grains was removed in a late case through an incision in the upper pole of the kidney which brought the operator directly upon the calculus. In another case the second calculus was found only because the exact localization led to the opening of a cyst in which it lay. In a third case three calculi were removed where one would have been considered the sole cause of the trouble. In two cases calculi have been found in both kidneys. Such precise localization would be invaluable in a case of partial or complete anuria from calculus. The knowledge obtained would facilitate and limit the extent and severity of the operation. The greatest value of this method lies in the mechanical method of its production, which guarantees mathematical accuracy when it is properly employed. If the calculus is suspected it can be detected. The examination is harmless, painless, and yet comprehensive, detecting or absolutely excluding calculi from all portions of the urinary tract.

The completeness and accuracy of these diagnoses, both positive and negative, has been attested by the seventeen cases, out of the twenty-four that have been operated upon. A calculus weighing 9/10 of a grain has been detected, and a mass of crystals that were not organized into a true calculus found and removed. Calculi of all chemical compositions are included in this number, from the more opaque oxalate to the less opaque uric-acid stones. Calculi have been found in fourteen cases; the negative diagnosis has been confirmed by seven operations, and in only one case, through a fault in placing the plate, has a calculus escaped detection.

The technique essential to the production of negatives upon which these absolute diagnoses can be based has been already published.[1] Where such mechanical results are produced, absolute dignosis can be based upon them. All that is essential is that the negatives be perfect in emulsion and show detail in shadows of tissues less dense than the least dense calculus.

The same method applies with equal accuracy to the detection of vesical calculi. It is especially valuable in determining the size and number of calculi present; in showing partially encysted calculi lying in a diverticulum or in detecting calculi in the pocket behind an enlarged prostate gland.

1930 Chestnut Street.

ACUTE TONSILLAR DISEASES AND THEIR SEQUELAE.*

JOSEPH H. ABRAHAM, M.D.
INSTRUCTOR IN LARYNGOLOGY IN THE NEW YORK POLYCLINIC.
NEW YORK CITY.

The tonsils belong to the hemopoietic system, and are germinating centers for the leucocytes. Their period of greatest activity is in childhood and youth, when all the lymphatic organs are especially active, and when the thymus gland is disappearing.[1]

Surrounding the tonsillar follicles are plexuses of lymphatics, and in the tissues of the tonsils there exists an intimate lymphatic network, composed of minute channels from which the lymph is collected by larger lymphatic vessels. These pass to the superior deep cervical glands, which frequently become enlarged in tonsillar inflammations, and can be easily demonstrated in the upper part of the neck. Goodale[2] proved that absorption exists normally in the tonsils and takes place through the mucous membrane of the crypts. Hodenpyl[3] demonstrated that rarefaction of the epithelium is of constant occurrence in the tonsils; as a result of this process, parts of the epithelium are considerably diminished in thickness. Therefore any irritant to the cells increases desquamation, which may denude the tonsil in places of its epithelial covering and favor lymphatic absorption of the toxins often found in this vicinity into the general circulation.

---

[1] Annals of Surgery, February, 1900.

*Read before the Alabama Medical Association, at Montgomery, Ala., April 17-20, 1900.

For practical purposes I have divided this paper into a description of acute catarrhal or superficial tonsillitis, acute lunar or cryptic tonsillitis, and peritonsillar abscess. Some knowledge of the relative frequency of tonsillar disease may be obtained from Lennox Browne's[4] hospital reports of 12,330 cases of tonsillar disease treated by him in ten years, representing 13 per cent. of all the cases of throat, nose, ear and neck diseases; of this number, 3167 cases were of acute or subacute inflammation, rather more than one-fourth of the whole.

Acute catarrhal inflammation of the tonsils occurs primarily as a lesion in acute pharyngitis and is found regularly in measles, scarlet fever and diphtheria. Secondary extension of an acute catarrhal and lacunar inflammation through the tonsils may produce phlegmonous tonsillitis; and in some cases the infection is primary.

Frequent bacteriologic examinations have demonstrated the presence of numerous micro-organisms within the lacunæ, among which streptococcus, staphyloccocus aureus et albus, Fränkel's pneumococcus, and Friedländer's pneumobacillus have been found.

In Meyer's[5] report of 53 cases, he found staphylococci in 14 cases, streptococci in 15 cases, and in the remaining 24 cases a mixture of the two. In 100 cases classified by Reid[4] at the Central London N. T. & E. Hospital, streptococci were found in 58 cases; staphylococci—aureus 31, albus 23, and others 8—were found in 62 cases. Diplococci were found in 32 cases. Among the other forms, Klebs-Loeffler bacilli were found in 7 cases.

Nicolle,[6] Hebert[6] and Pakes[7] inoculated serum tubes from the throats of patients and found Friedlander's pneumobacilli were present 8 and 5 times, while Griffon and Besancon examined the tonsillar secretions of 40 persons of all ages and conditions, and found the pneumococcus constantly present.

Sendziok[9] examined 133 cases of lacunar tonsillitis and found staphylococci and streptococci were constantly present. He also found that hypertrophic tonsillitis predisposed to an attack and that the disease was equally divided between the two sexes, but a majority occurred between the ages of 20 and 30. Out of 1000 cases reported by Mackenzie,[10] 323 cases occurred between the ages of 20 and 25, and 184 cases between 15 and 20. Persons once affected are very liable to subsequent attacks.

Patients suffering from congenital or acquired hypertrophy of the tonsils are very prone to an attack. Retained masses within the lacunæ may produce an irritation favoring inflammation.

Lymphatic hypertrophies in the vault of the pharynx, causing mouth-breathing, thereby lowering the normal physiologic function of the gland, predispose to an attack. In four cases of recurring lacunar tonsillitis in children, I have obtained a complete cure by removing the adenoids.

Edwards and Severn[11] reported six cases of milk infection, causing acute lacunar tonsillitis, and traced the infection to one particular cow in the dairy. In the milk were found the same micro-organisms as were found in the exudates from the tonsils.

Chapin[12] considers disordered stomach due to overfeeding, producing an acid fermentation as a frequent cause of tonsillitis in children. A rheumatic, gouty and strumous diathesis and other conditions, as over-work, mental depression and menstrual—Gautier[13] and Raymond[14]—disorders are predisposing causes; in some, by the action of the toxic substance in the blood upon the lymphatic tissues of the glands; in others, by reducing the normal physiologic resistance of the mucous membrane of the tonsils, allowing previous non-virulent bacteria to assume a virulent type and favoring absorption into the system of their toxins.

The exciting causes are exposures to cold or sudden thermo-climatic changes, and vary considerably in different localities.

In comparing Delavan's and Mackenzie's[15] tables, Delavan finds that tonsillitis is most frequent in March, least frequent in September, in New York; Mackenzie finds nearly the opposite conditions existing in London.

Inflammatory changes, due to mechanical irritation and inhalation of irritating gases may be a direct cause. Frankel and Lennox Browne[16] consider intranasal operations a frequent cause, and especially after the use of the galvanocautery. Lastly, bad hygienic surroundings favor an attack, as the following will prove:

In December, 1898, I was called to see a girl, aged 7, suffering from an attack of acute lacunar tonsillitis. At the end of twenty-four hours the entire household—two girls, three adults and a servant—were affected. The drain-pipe of the refrigerator was connected with the house drain, and for several days the family had noticed a peculiar taste and odor in the milk, butter, etc. The drainage was corrected, the refrigerator cleaned and no subsequent attacks occurred.

The various forms of acute inflammation of the tonsils vary mainly in degree. The edema of the tonsils is due to the engorged vessels which cause obstruction of the muciparous glands, and it is followed by infiltration of the parenchymatous tissues with an exudate of serum and leucocytes. In lacunar tonsillitis, the epithelium is thus deprived of its nutrition, the cells become swollen and cloudy, followed by rapid multiplication and death, producing the yellowish masses we see upon the surface of the tonsils and so pathognomonic of the disease. Leucocytes, numerous micro-organisms—see Etiology—and at times fibrin are found in the exudate. Sometimes these coalesce and cover the tonsils with a serofibrinous exudate, resembling a membrane. Transudation of the leucocytes occurs to such an extent in the parenchymatous tissues that it is impossible to differentiate the lymph-nodules from the surrounding lymphatic tissues. This, in conjunction with the engorged vascular supply, increases the size of the tonsils. As a result of the infiltration, the cells die, pus is produced in the substance of the tonsils, or, as occurs most frequently, the inflammation may extend externally and involve the intercellular spaces, following the coagulation-necrosis, with the formation of a peritonsillar abscess.

In the majority of cases we find great prostration and severe constitutional symptoms, which are entirely out of proportion to the local manifestations. Usually the person complains of chilly sensations, which at times may be a distinct rigor, these with headaches, aching pains in the back and extremities, followed by a feeling of dryness in the throat and of stiffness in the muscles of the neck, are usually the premonitory symptoms. Following the onset, pain in the throat is the most frequent symptom; it is lancinating in character, and located more at the angle of the inferior maxilla. The pain is often reflected to the ear, and follows an extension of the inflammation to the mucous membrane lining the Eustachian tube, producing a catarrhal otitis media with tinnitis and a temporary impairment of hearing. When the inflammation attacks the laryngeal structures the voice will be altered; this is especially true when the swelling of the pharyngeal structures interferes with the nasal resonance. The temperature rises rapidly, and in children may reach as high as 105 F.; in adults the temperature varies from 101 to 103 F. The tongue is furred, the breath foul and there is often vomiting and diarrhea in infants, while older persons complain of nausea and obstinate constipation. The pulse is full and regular, and averages 100 to 120. The amount of urine is decreased; it is highly colored, loaded with urates and contains an excess of urea. A great amount of indican may be found, but there is a deficiency of chlorids. Albumin is occasionally found in small amounts. On examination the tonsils are found to be swollen and the mucous membrane deeply reddened. Scattered over the surface are seen the characteristic yellowish masses, marking the orifices of the lacunæ; sometimes they coalesce, forming a creamy exudate, resembling a membrane. A slight swelling and tenderness of the cervical glands may be found. Osler[17] considers the development of general or local paralytic symptoms in lacunar tonsillitis as proof of an error in diagnosis. The general symptoms continue for from one to three days, when the inflammation subsides, the fever departs and the local conditions improve.

In the peritonsillar abscess the symptoms vary greatly in severity from those of an acute catarrhal and lacunar tonsillitis. Frequently the symptoms of the latter precede those of the former from one to three days or more. The pain in the throat is deep-seated and throbbing or boring in character. Dysphagia is intense, the patient can hardly swallow his own saliva and refuses food on account of the swelling and severe pain on opening his mouth. The breath is very foul, the tongue covered with a thick, furry yellowish-gray or brownish material, the teeth are covered with sordes, and the general expression is one of great anxiety and suffering.

Locally, the tonsils and surrounding structures, the uvula and velum palati and frequently the laryngeal structures are reddened and edematous. As suppuration increases, the swelling of the cervical glands and surrounding tissues also increases and spontaneous rupture may occur at the most dependent portion.

The differential diagnosis between lacunar tonsillitis and diphtheria is at times extremely difficult. Upon clinical and bacteriologic examinations rests our diagnosis; therefore, in all doubtful cases cultures should be made, that the presence or absence of Klebs-Lœffler bacillus may be determined. In some cases of diphtheria, the bacilli may not be found at the first examination, but subsequent examinations will reveal them; again, the presence of the pseudo-diphtheria bacillus makes positive diagnosis somewhat doubtful. The majority of physicians must rely entirely upon a clinical diagnosis, and in order to do this an enumeration of the following local and constitutional symptoms will aid. A history of repeated attacks is common in tonsillitis, seldom so in diphtheria; as a rule, the onset of diphtheria is gradual, with a low temperature, rarely over 103 F., which continues for some time; the pulse is rapid, depressed and at times irregular. In lacunar tonsillitis the onset is usually abrupt, with a high temperature, which may reach 106 F. early in the disease. The pulse is rapid, full and regular. With the low temperature of diphtheria, albumin appears early and persists for a considerable length of time, while with the high temperature of tonsillitis it is rarely found; if so, usually about the second day, and only lasts from twenty-four to forty-eight hours. The membrane of diphtheria begins as a small patch, usually of a pearl gray or of a dense white color. It soon spreads to the faucial pillars and uvula and on removing the membrane the surface bleeds and is eroded.

In lacunar tonsillitis the exudate is of a yellowish color and marks the orifices of the lacunæ. It can be easily removed, leaving no bleeding or eroded surface. In diphtheria, frequent paralysis of the throat and other muscles with marked asthenia, and severe toxemia are found. In tonsillitis they rarely, if ever, occur.

At the onset tonsillitis may be confounded with scarlet fever, but the characteristic exanthema and tongue symptoms of the latter will clear the diagnosis.

Recent clinical and bacteriological evidence proves that the tonsils are without a doubt portals through which pathogenic micro-organisms enter the system, and that infectious diseases and serious sequelæ may result therefrom. Du Mesnil de Rochmont[18] reviews the recent literature on the bacteriological investigations as well as the complications following acute tonsillar affections. Among the latter, he mentions the following: Pleuropneumonia, osteomyletis, albuminuria, paraplegia, erysipelas, orchitis, etc. The same author reports an epidemic of acute tonsillitis in the Altonia hospital, following the admission of a patient suffering with acute tonsillitis and acute articular rheumatism. A few days later 17 patients and a nurse, in five wards in the same corridor, developed acute tonsillitis. No case of tonsillitis existed prior to the above, therefore the infection seemed clear.

Cultures from the tonsillar exudates demonstrated the presence of staphylococci, streptococci and a few small non-pathogenic streptobacilli. Following the tonsillitis, three cases developed acute rheumatism, one nephritis, pericarditis, endocarditis and myocarditis. In concluding his article, he advocates isolation in all cases of acute lacunar tonsillitis.

In 1866 Trousseau called the attention of the profession to the fact that acute tonsillitis frequently precedes an attack of rheumatic fever: since then numerous investigations have verified his deductions, therefore if we accept the theory that rheumatic fever is an infectious disease, then the following evidence will prove that rheumatism is frequently a sequel of acute tonsillitis.

Sir Willoughby Wade[19] claims that rheumatic fever is a secondary disease arising from the absorption of microbes or their toxins into the system and frequently follows a primary infection of the tonsils. In support of his views, he reports a number of cases of rheumatism following the first attack of tonsillitis, while other cases followed after repeated attacks, in which no previous history of rheumatism existed. Wagner[20] reports two interesting cases of tonsillitis, without previous histories of rheumatism, in which, after a bacteriologic examination, the same micro-organisms were found in the knee-joint and urine as in the diseased tonsils. Sterling[21] mentions five cases and Ross[22] four cases of rheumatism following acute lacunar tonsillitis.

Between the years of 1890 and 1898 Lachmanski[23] studied seventy-three cases of acute rheumatism in children at the Emperor and Empress Frederick Hospital in Berlin and found twenty-six cases were due to exposure to cold and other causes. In eleven cases pharyngitis, in two lacunar tonsillitis were the causes. In three cases tonsillitis occurred between attacks of articular rheumatism.

To the above I add another:

Miss ——, aged 24, professional nurse, complained of a sore throat. On examination her pharynx and tonsils were reddened and swollen. Protruding on the surface of the glands, the characteristic yellowish exudates were seen. Her temperature was 102.8 F. With a decline of the faucial symptoms, there appeared on the third day pain and swelling in her right shoulder, which appeared subsequently in the left shoulder, knee and ankle joints. The patient gave a good family history, but had suffered previously from two attacks of tonsillitis, never from rheumatism.

M'Donnell[24] reports a case of acute tonsillitis followed by pericarditis without arthritis, and Jessen[25] mentions a case of pericarditis with a double pneumonia which proved fatal following a staphylococcus tonsillitis. Packard[26] reports seven cases of tonsillitis followed by endocarditis. In five of the cases he was positive that there existed no abnormal heart lesions previous to the attack of tonsillitis. Mayer [27] reports a case of lacunar tonsillitis followed by endocarditis. Holt[28] reports a case of cardiac murmur, following an attack of tonsillitis. In both cases the heart was previously normal, and no articular symptoms existed. Out of 120 cases of tonsillitis reported by Roeger,[29] 24 developed a cardiac murmur, 14 commenced and terminated with the tonsillitis, ten persisted later.

The following case occurred in my own practice:

A girl, aged 8, complained of a headache, with severe chill and sore throat. On examination the tonsils presented the yellowish plugs and were quite edematous and reddened. Temperature 105.2 F., pulse 120. Under treatment the temperature fell to 101 F. in twenty-four hours. On the third day all local symptoms had seemingly disappeared, but on examining the heart a loud systolic murmur was heard distinctly at the apex and transmitted to the left. On the fourth day, articular symptoms appeared in the left knee and ankle joints, and on the tenth day a marked case of chorea had developed. On the mother's side a family history of rheumatism existed, although the child had never suffered from articular pains or any heart murmurs previous to this attack.

B. Abrahams[30] reports 248 cases of corea, of which 53.4 per cent. had a family or personal history of sore throat.

Heddaeus[31] reports a case of metastatic pleurisy following an attack of acute tonsillitis, due to staphylococcus pyogenes aureus, and Jessen[25] mentions a case of wandering pneumonia, pleurisy, and nephritis following a streptococcus tonsillitis.

Baduel[32] reports 4 cases of tonsillitis due to the diplococcus of Fränkel, which was found in the blood, nephritis following later.

Hollick[33] reports a fatal case of tuberculous meningitis following tonsillo-glossitis, and Fagge[34] mentions a case somewhat similar.

Zilgien [35] reports 4 cases of tonsillitis, followed by angina pectoris.

Troquart[36] mentions 2 cases of suppurative adenitis, and Vergely[36] one case after an attack of acute tonsillitis.

Delavan[15] reports a case of edema of the glottis following peritonsillar abscess, which proved fatal.

Hamilton[37] reports a case of convulsions in a 7-year-old girl following a case of acute suppurative tonsillitis.

Sendziok[38] reports a number of cases of laryngitis and bronchitis complicating acute lacunar tonsillitis.

Buschke[39] and Jessen[25] mention cases of osteomyletis following streptococcus and staphylococcus tonsillitis.

Ward[40] reports a fatal case of septic thrombophlebitis following a peritonsillar abscess. Bosworth[41] reviews the literature of the complications following peritonsillar abscess and mentions a number of investigations whose cases are somewhat similar to those reported under lacunar tonsillitis.

The proofs presented in this paper establish the etiologic factors of some of the infectious diseases as well as other sequelæ and complications arising from an acute attack of tonsillitis. Our duty is to prevent such infections, to investigate carefully each case of tonsillar disease, to reconsider and classify them as more than innocent affections, and in future to treat the attack energetically, and assiduously apply the proper local general and operative treatment in the interim.

At the onset of acute catarrhal tonsillitis, administer a saline purgative; spray or brush the tonsils and pharynx every hour with a solution of:

℞. Formalin ....m. xv-xx
Potass. chlor...............................ʒi
Liq. ferri. chlor..............................ʒi
Aquæ menthæ pip. q. s. ad...................℥iv
M. Sig. Use as spray.

Early in the disease cold applied internally in the form of gargles or cracked ice in the mouth, and externally in the form of cold compress or ice bag is of invaluable aid. The patient should drink frequently of equal portions of cold milk and vichy. For the febrile condition administer anitpyrin, and in conjunction give a capsule containing:

℞. Quinin hydrobromat.......................gr. i
Sodii benzoatis............................gr. ii
Salol ....gr. v
M. et. ft. cap. No. i. Sig. One every three hours.

If the inflammation extends to the deeper tissues, the tonsils and surrounding structures become edematous and interfere with deglutition. Multiple punctures and scarifications are then indicated in order to produce free bleeding, and at this stage heat applied internally, in the form of gargles and hot drinks, and externally, in the form of poultices and fomentations, is indicated.

In the remaining forms of tonsillitis, much depends upon the stage of the disease. If we begin treatment within twenty-four hours of the onset, we can frequently abort the attack by administering at once a tablet containing calomel, gr. ¼, and sodium bicarbonate, gr. 1, every thirty minutes for eight doses, followed later by a Seidlitz powder. Remove with a curette the yellowish exudate from the crypts, and apply on a cotton-tipped probe to the surface and into the crypts of the tonsils every two hours the following:

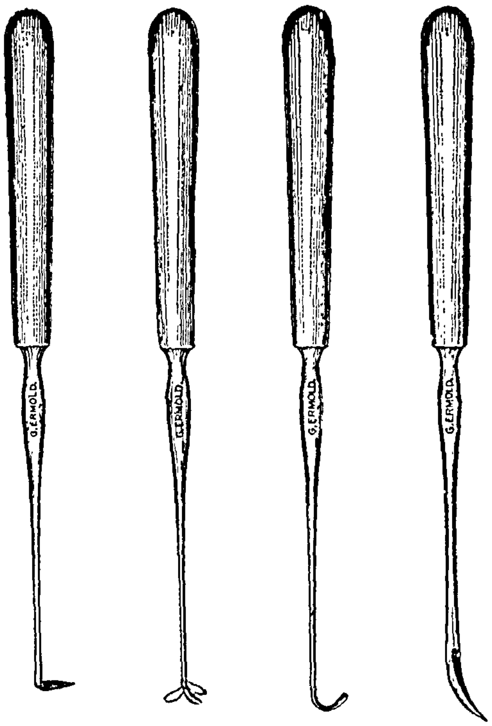
℞. Menthol ....ʒss
Guaiacol ....ʒiss
Glycerin ....ʒii
Alcohol Absol. q. s. ad...................℥i
M. Sig. Apply locally.

Cold should be applied immediately. Administer every half-hour half a drop of tr. aconite and watch carefully for the physiologic effects of the drug, stopping immediately upon their appearance. Give internally every two hours, in a little milk or water:

℞. Guaiacol carb.........................gr. i
Sodii benzoat..........................gr. ii
Sodii salicylat.........................gr. v
M. ft. Pulv. No. i. Sig. In milk or water every two hours.

Pus should be evacuated as early as we can diagnose its presence; tonsillar abscesses should be incised with a sharp-pointed knife and sprayed with the compound formalin solution. A peritonsillar abscess should be opened with a sharp-pointed curved bistoury protected with a piece of cotton or adhesive plaster, so as to expose only the cutting surface, the incision being made where the abscess points or at the most dependent portion. The direction of the incision should be from above downward and slightly outward parallel with the anterior pillar.

The isolation of all cases of acute lacunar tonsillitis is advisable. In adults and children recurring tonsillitis and inflamed and hypertrophied tonsils are positive indications for a radical procedure. When all acute symptoms have subsided, subsequent attacks should be prevented by a partial or complete removal of all tonsillar tissue. Hypertrophied tonsils with numerous crypts, and spongy surface, that we so often see in children or young adults, should be amputated, either with the tonsillotome or with the galvanocautery wire or knife. If the former instruments are employed, I invariably cauterize the cut surface in from ten to twenty days with a galvanocautery knife, so as to form a dense cicatrix and to eliminate the remaining crypts. Hypertrophied tonsils in adults, with a ragged surface, enlarged crypts and broad base should be removed entirely. The adhesive fold of mucous membrane which is frequently attached to the anterior faucial pillar and inner surface of the tonsil should be incised with the right-angled knife, and the tonsil removed with a gouge. The after-treatment consists in keeping the parts thoroughly cleansed with the compound formalin solution.



The conclusions to be derived from a study of these affections are: 1. All cases of acute tonsillar disease should be considered more than trivial affections. 2. Acute lacunar tonsillitis is an infectious disease. 3. Isolation should be practiced in all cases of acute lacunar tonsillitis. 4. Recurring attacks of acute tonsillitis are an indication for the partial or complete removal of the tonsils. 5. A careful systemic examination and treatment should be applied during and after an attack of acute tonsillitis.

SARCOMA OF THE STOMACH.*

BY GEORGE DOCK, M.D.

Professor of Medicine in the University of Michigan.
ANN ARBOR, MICH.

T. J. W., a male, married, merchant, 55 years old, was admitted to the University Hospital Jan. 18, 1900, on account of loss of strength and weight, and distention, burning pain and tumor in the region of the stomach.

The family history is negative. In early life, he had whooping-cough and measles, and while in the army during the Civil War, he had several attacks of intermittent fever, and was jaundiced four months. Ever since then he has been constipated. Up to two years ago he had every summer an attack of pain in the abdomen, with vomiting, fever, pain in the head and back, ending with diarrhea, but he has never had jaundice after these attacks.

During the last four years, he was postmaster and had long hours. He ate hurriedly and heartily, almost without mastication; and thinks that this has aggravated his present disease. He uses tea and coffee in moderation, and smokes, but does not use alcoholics.

The present disease began in December, 1897. Constipation was very troublesome and he lost weight. Soon after this, he noticed a heavy sensation in the stomach region. In the spring of 1898, he had an attack of pain in the right hypochondrium, moving down toward the hip; it was cutting and of short duration, but was followed by pain and tenderness in the liver region, in the back and in the right side of the abdomen. He never had nausea in the attacks, but the pain made him double up. He had a number of very severe attacks of this kind, and gall-stones were suspected, but were never found in the stools. In April, 1898, he began to vomit, and at first only what had been last eaten; but later, articles eaten a day or so before, but never blood or dark material. He had regurgitation of an irritating fluid.

In July, 1898, a tumor was discovered just below the ribs in the right nipple line. This he thinks grew smaller, but during all this year the abdomen was distended more or less. In December, 1898, at the advice of a friend, he began to use the stomach-tube, washing out the stomach three times a week before breakfast. This gave much relief, but was associated with great loss of weight. By the end of three weeks he had lost from twenty-five to thirty pounds, had no appetite and could take nothing but milk. He was then treated by a physician, who stopped the lavage, gave strychnia, laxatives, etc., and looked after the diet. He then improved, gaining thirty-five pounds in four months, and the pain almost disappeared. In October, 1899, he began to vomit after almost every meal, lost weight and strength and his appetite failed. The stomach became greatly distended, and a sour, burning fluid was regurgitated. Food-remains of the day before were found in the vomitus, but there was never any blood. He thinks the tumor is no larger than when first noticed.

---

*Read before the Association of American Physicians, Washington, D. C., May 3, 1900.

Present state.—Jan. 18, 1900. The patient is 5 ft. 6 in. in height; weighs 110 pounds; the frame is of medium size; panniculus is absent; the muscles are small and flabby; the skin is loose, inelastic, rough, dry and sallow; and there is marked nodular myoidema. The mind is clear, but the expression is languid. There is marked arcus senilis. The visible mucous membranes are pale; there is no edema; no enlarged glands, and the joints are normal. The tongue is not large, and the papillæ are not enlarged, while the surface is moist and covered with a thin, white coat. The teeth are defective, and he has an upper plate. The thorax is of medium size and well-formed. Auscultation and percussion of lungs and heart are negative. The radial arteries are tortuous, and the walls uneven. The pulse is 64, and regular, with moderate tension. The abdomen in general is below the level of the ribs; but above the umbilicus, tumors of considerable size form and disappear, move from right to left, back to right and downward. They can easily be brought out by tapping on the abdomen. Auscultatory percussion shows change of note an inch below the navel. There is succussion to the line of the umbilicus. Just below the edge of the ribs, between the right nipple and parasternal lines, is a mass about the size of a hen's egg, hard and smooth; it moves down with inspiration and is retracted with considerable force in expiration. Liver dulness extends from the sixth interspace to the edge of the ribs, and the organ can not be felt. The splenic dulness is small, and the spleen can not be felt. but the right kidney can be in deep breathing. The blood flows freely and is of good color. The red corpuscles number 4,960,000; the leucocytes 7250; the hemoglobin (Fleischl) is 75; the sp. g. is 1056. The differential count of leucocytes shows lymphocytes 7 per cent., polymorphonuclear 89, transition 2, and degenerates 2.

Jan. 18, 10. p. m. The stomach was prepared for Boas' gruel. At same time 700 c.c. of fluid was aspirated; the first part was light, but later was darker, with acid odor, much foam, and gas bubbles breaking after standing. The lower layer was of white granular material, with undigested meat, potatoes and milk; the middle one was of a clear, pale yellow fluid; and top of foamy mucus with sarcines and yeasts, fat, muscle-fibers and starch. There was no blood; no pus; and no tissue.

Jan. 19. Boas' breakfast was aspirated after 45 minutes. The findings were: 200 c.c. of a pale yellow, cloudy fluid, with an odor of apples; reaction, acid to litmus; congo, dark blue; Günzberg, negative; dimethyl, positive; Uffelmann, negative; total acidity, 51 = .18615; combined acid, 7 = .02555; free HCl, 28.5 = .10402; organic acids and acid salts, 15.5 = .05657. Digestion in a test-tube was very slow, even with the addition of HCl. The sediment consisted of food remains, a few leucocytes, and some very small bacilli (not Oppler-Boas).

The stomach was distended with CO_2. The lesser curvature was just above the umbilicus; the greater one, four inches below; the stomach was perpendicular; the tumor was behind the right end of the distended stomach.

The urine examination showed an excess of indican; otherwise it was negative; and the examination of the stools was also negative. The patient was given special diet for dilatation.

Jan. 21. Boas' meal was given and was aspirated after one-half hour. The findings were: 400 c.c. of a dark yellowish-brown fluid, containing food particles and sarcines; Günzberg, positive; the quantitative tests about as before; digestion in test-tube slower than before.

Lavage was repeated every two or three days, according to the indications, and there was always more or less fermentation, with sarcines. Hydrochloric acid was always present, but lactic, never. The patient gained three pounds in ten days, and the tumors ceased forming in peristalsis.

The diagnosis was dilatation from tumor at the pylorus, probably the scar of an old ulcer. When admitted, the patient laid much stress on the history of a paroxysmal pain, with a soreness in the epigastrium, vomiting, etc. Although there was no history of hemorrhage, the symptoms in the early stages had not been carefully observed. There was evidently an adhesion between the liver and the stomach tumor, and on account of the history, long duration and absence of more positive evidences of malignancy, I thought this pointed rather to a hypertrophic scar than to a new growth. Largely on the ground of probability, the likelihood of a carcinoma being present in the tumor was represented to the patient; and other possibilities, especially sarcoma, were considered, but the features of the case were not considered to admit a differential diagnosis.

The patient was advised to submit to an operation, with a view to carrying out the best treatment permitted by the local conditions when examined directly. He consented, and pylorectomy was made by my colleague, Dr. C. B. Nancrede, professor of surgery in the University of Michigan. The operation, having been unavoidably postponed, was done Feb. 5, 1900. The part removed represented about one-third of the long axis of the stomach and about 2 cm. of the duodenum, while the tissue seemed to be well clear of new growth at its extremities. No metastases could be found, and uninterrupted recovery followed the operation. The patient sat up in three weeks and was discharged in five, having gained the weight lost after the operation, and his weight was still increasing rapidly.*

The piece of tissue removed measured 6 cm. along the lesser curvature. The pylorus was almost closed, and projecting into the lumen was a tumor of oval shape about 6 by 4.5 cm. in diameter, occupying the posterior wall of the stomach. The serosa behind the mass was covered by stringy adhesions which had been separated at the operation. The tumor was smooth and elastic, and on section showed a grayish white, almost homogeneous surface, yielding few cells on scraping. Near the main mass were several smaller nodules having similar macroscopic characters. The mucosa in the uninvolved part of the stomach was thick and uneven, while over the tumors it was smooth, and in some places red, but nowhere eroded or ulcerated. Section showed the new growths to be chiefly in the submucosa and muscularis. Microscopically, the tumor was a lymphosarcoma, with a well-developed reticulum containing small cells in its meshes.

The new growth invades the muscularis, but does not show a tendency to affect the mucosa, which, in parts distant from the tumor, shows interstitial infiltration without evidences of sarcomatous formation.

Sarcoma of the stomach is not often reported. Schlesinger,[1] who made a careful study of the subject in 1897, was able to find references to only 33 cases, to which he added 3 of his own. I have found records of 10 other cases in periodic literature, 3 of which (5, 10 and 13) I have not been able to obtain, besides a few briefly mentioned in text-books. I refer to three of the latter.

---

*Note on revision of proof, June 30, 1900: I have just examined the patient, who weighs 140 lbs., or more than ever before. He is free from symptoms, can eat anything. Physical examination shows slight induration at the seat of the operation, apparently only the remains of the operation scar.

One of the cases cited by Schlesinger (Hardy) seems to have been carcinoma, as Tilger has suggested. On the other hand, it is probable, as Brooks says, that cases of sarcoma have been incorrectly reported under the name of cancer.

The absolute rarity of the affection is beyond question, and the only reason for calling attention to it again is to ascertain whether recent additions make it necessary to revise the older views. This is all the more needful because the present case differs in certain respects, notably in the results of the analysis of the stomach contents, from those previously reported.

In the following it is unavoidable that I follow Schlesinger closely, since my examination of the literature largely confirms his conclusions. I cheerfully acknowledge my obligation to his excellent article, and refer to it for the earlier literature.

Sarcoma of the stomach may be primary or secondary, and the latter is perhaps more frequent than secondary carcinoma, but it is rarely of clinical interest. Sarcomata of several varieties have been found as primary growths in the stomach, i. e., spindle-celled, fibro-, myo-, myxo-, angio-, and round-celled sarcomata. The majority of the latter were probably lymphosarcomata.

The primary growth may originate in any part of the stomach. Schlesinger found the greater curvature often involved, especially by the varieties that form tumor-masses rather than flat infiltrations. In several recent cases, the round-celled or lymphosarcomata developed in the pyloric region, and some of the others in the posterior wall. The reported cases are too few to establish rules regarding location, such as are admitted in the case of cancer.

As regards size, the tumors vary greatly, but a rather large proportion reached a size unusual for gastric tumors. In Brodowski's case and also in Cantwell's,[11] the tumor weighed 12 pounds. In Baldy's[8] the mass filled the abdomen from the ensiform to the pubis. The growth begins in most cases in the submucosa, or less frequently in the muscularis.

Primary lymphosarcoma of the stomach sometimes produces extensive flat infiltrations or local thickenings, or as in the present case, circumscribed tumors. The mucosa is rarely involved early, but may be stretched or its nutrition injured by pressure, causing it to ulcerate. In some cases, the tumor projects outward. Softening is not unusual, especially in the larger tumors. Suppuration may also occur, and in either case, peritonitis from rupture may follow, but in some cases rupture has occurred into the cavity of the stomach.

Metastases occur, as in other sarcomata, and may be found in the neck, pharynx, or in other parts of the abdomen. In some cases, even with primary lymphosarcoma, the disease has lasted a long time without metastases.

As regards age, Schlesinger found lymphosarcoma of the stomach most frequent between 20 and 35; other varieties, somewhat later. In Finlayson's case[10] a rickety and feeble child was affected at 3 years of age and died 6 months later, while in Westphalen's case[2] of myxosarcoma the patient was 28.

Men are more frequently affected with this disease than are women. The study of it throws no light, as yet, on the cause. In Brooks' case[9] the disease began, apparently, in the scar of a bullet wound, acquired many years before.

Our knowledge of the clinical features is even more meager than that of the anatomical facts, since only a small proportion of cases were carefully examined during life.

The mode of onset varies, but is often insidious. Thus, in Baldy's remarkable case[8] the stomach had "never given the patient a day's trouble," the appetite was voracious and there was no vomiting; in Cantwell's also, there were no gastric symptoms. In both the disease began in the posterior wall. Later, such symptoms as loss of appetite, vomiting, and pain of various kinds and various degrees of intensity occur. The pain may be referred to the epigastrium or the back. Hemorrhage is almost never an early symptom, but when it occurs may have the different characteristics that present themselves in cancer—the blood resembling coffee-grounds, or being fresh or clotted. In Hartley's case[4] there was a history of coffee-ground vomiting five years before, after long-standing dyspeptic symptoms. A year before the operation, at which the mucosa was found not ulcerated, there was vomiting of coffee-ground material and also clots. Blood, more or less altered, may also appear in the stools.

If there is a tumor it presents the same variety of physical conditions as carcinoma except in cases with colossal growth, when the relations may be impossible to make out clinically and difficult to understand at an exploratory operation. If in the pyloric region, obstruction, dilatation, increased peristalsis, stagnation and decomposition, lessened diuresis, concentration of the blood, even tetany, may result. Dilatation may occur without obstruction, in the case of wide-spread infiltration.

Examinations of the stomach contents have been made in only a few cases, and in all but the present one —nine others reported—free HCl was absent, and in most of them lactic acid was present. In one of Schlesinger's cases, there was free HCl in the beginning, but it disappeared. Sarcines were absent from the others as a rule, and in one of Schlesinger's, long bacilli were present. In some cases, there was no blood in the stomach contents, but in others there was, so that the resemblance to the findings in carcinoma is very close. As far as the present case is concerned, the presence of free hydrochloric acid and sarcines does not materially weaken the conclusion that the stomach contents in both carcinoma and sarcoma have the same characteristics, since it has long been known that absence of hydrochloric acid and presence of lactic acid are not due to the carcinoma as such. In fact, the conditions observed in my case are found in some of carcinoma of the pylorus up to a late period.

The blood in the cases of sarcoma of the stomach hitherto examined showed diminished red cells and hemoglobin and usually leucocytosis. No examinations seem to have been made regarding digestion leucocytosis.

The average duration of the disease is 1 to 1½ years.

The diagnosis of sarcoma of the stomach has rarely been made during life. In the case of Westphalen, it was based on the microscopic examination of a bit of tissue; and in one of Schlesinger's, the diagnosis of lymphosarcoma was made, based on supposed metastatic growths in the intestine and lymphatic glands and enlarged spleen. Autopsy revealed myosarcoma with suppuration and perforation of the stomach. There were a few retroperitoneal metastases. Riegel mentions[14] a case in which a large sarcoma nodule was vomited and the diagnosis made. There were in the same case metastases in the skin, but the danger of depending on such co-existing tumors is made clear by von Leube,[15] who found, in one case, sarcoma in the skin and an epithelial tumor in the stomach.

This symptom is probably as little reliable as two others mentioned by Schlesinger—enlargement of the spleen and swelling of the follicles of the tongue, both thought by Kundrat to be common in lymphosarcoma. They may sometimes enable one to correctly recognize gastric sarcoma in a late stage, but so far as the earlier stages are concerned we have no specific symptoms of sarcoma of the stomach, and even when tumor is present it can not be positively differentiated from cancer. It is important to discover the affection of the wall early, and if possible to carry out either radical or palliative operative treatment, without taking time to make a histological diagnosis from the clinical features. If discovered too late for this, the treatment must follow the same general lines as for other tumors of the stomach. The results of operations compare favorably with those for other malignant stomach diseases. In Cantwell's case, a spindle-celled sarcoma involving five inches square of the stomach wall was removed. The patient was free from symptoms for six months after the operation, and then a secondary tumor was discovered.

VALUE OF THE ANGIOTRIBE IN VAGINAL CELIOTOMY.*

J. H. CARSTENS, M.D.

DETROIT, MICH.

When Battey first suggested the removal of the normal ovaries in cases of otherwise incurable dysmenorrhea, he performed his operations through the vagina; Hegar and Tait at the same time performed a similar operation but by means of abdominal section; the latter especially perfected the operation by the abdominal route for the removal of the uterine appendages in pus cases. This was the beginning of modern abdominal surgery, and the gynecologists of the past few years became pelvic surgeons, removing tubes and ovaries for all kinds of conditions and symptoms; but the extreme swing of the pendulum has been reached; conservative surgery predominates, and efforts are made to preserve half or at least a part of the generative organs.

The state of perfection to which American surgeons brought celiotomy caused the neglect of the original route suggested by Battey, until, by the effort of the French surgeons, especially, the vaginal route was again brought forward, not only for the relief of cancer, but also for inflammatory and suppurative conditions of the pelvic organs. The extreme French suggestions have in turn reached their limit; and cases are now carefully selected for one route or the other by all able and experienced surgeons.

Battey called his original operation "normal ovarian section," with the idea that the ovaries he removed were normal, but modern investigation has shown that while the ovaries may appear normal macroscopically, sections under the microscope show abnormal conditions. This accounts for the pain, distress and symptoms produced by these structures; we find a good many cases where a woman will complain of a great deal of pain in one ovary, continuing for years and causing a great deal of distress, when by palpitation we can not find anything. Experience has taught us that the removal of that ovary will cure the patient; and the microscope will show that the ovary was diseased. To remove the diseased ovary by abdominal section, witn the acompanying dangers and sequelæ, seemed to me poor practice; so I followed the Germans, performing, in selected cases, what they call vaginal celiotomy. But I have encountered one great trouble, and that is to tie the broad ligament and control the hemorrhage, especially in cases of narrow vaginæ. If the abdomen be entered between the uterus and bladder, or behind them, it is not easy to remove the diseased tube and ovary when they are in the cul-de-sac; and it is very difficult to apply the ligature to the broad ligament and tie it sufficiently tight to control the hemorrhage; so that I have been obliged, in some cases, to apply a clamp and leave it on forty-eight hours. This, of course, frequently causes sloughing of the compressed part and adhesion posteriorly, and prolongs convalescence.

When the angiotribe was first brought forward by Tuffier I was sure here was the instrument which would enable us to frequently perform vaginal operations, where formerly we would have been obliged to do an abdominal section. Take, for instance, the case of a young girl who has fallen from a swing or bicycle and has dislocated the ovary into the cul-de-sac: there it is; you can not get it back; and if you do, it will soon drop again into the abnormal position; with every defecation there is pain; every month a few days are spent in bed, and there is constant misery and suffering.

I have tried all kinds of treatment and the only thing I see to do, as a rule, is to remove the ovary. To do that by abdominal section and leave a scar is certainly not desirable. With a small opening in the cul-de-sac, you can pull down the ovary and tube, apply your angiotribe, crush the tissue, and cut off the diseased parts. It takes only a few minutes, and in a few days the patient is well with nothing to show that she ever underwent an operation, while the danger is virtually *nil.*

When I went to Europe last year, I thought I would investigate the subject and select whatever instrument I thought best. I examined the [illegible] Doyen, He[illegible] and Thumin—of Berlin—and [illegible] have selected as the best. It has a narrow blade of great strength, and instead of a wheel, where your power to crush is limited, it has a small handled lever, which gives you an immense power and is less trouble to apply and hold in exact place than the others; at least it seems so to me. With a little practice you soon get the knack of it and can use it without trouble. I have used this in abdominal hysterectomy without ligatures, and I have used it in vaginal hysterectomy without using a single ligature, so that I consider it perfectly safe to control hemorrhage, but ocasionally, if I had a bleeding point that I could not reach and was suspicous of, I would apply an extra ligature. I would not endanger my patient's life by taking any chances, but as a rule I have been able to perform these various operations without the use of a single ligature or clamp, simply by the use of Thuman's angiotribe.

---

*Presented to the Section on Obstetrics and Diseases of Women, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

I mention these cases to impress you with the perfect safety of the instrument; its greatest use, however, has been in the removal of small ovarian tumors, of diseased ovaries in the cul-de-sac, and of pus tubes which were between the uterus and rectum. All these could be readily pulled out, the angiotribe be applied to the pedicle, and a strip of gauze introduced, which was allowed to remain for four or five days.

I will not burden you with a report of a number of cases. I simply want to urge a further trial, so that the real status of this instrument may be fixed. I am sure that it will be found to lessen the period of convalescence in pelvic surgery and to save more lives than any instrument hitherto devised.

Therapeutics.

Vulvitis.

℞. Liquoris plumbi subacetatis..................ʒi
Tinct. hyoscyami..........................ʒii
Aq. camphoræ, q. s. ad....................℥viii

M. et. ft. lotio. Sig. Apply with saturated cloth.—*Waring: Medical Record.*

Superficial Burns.

Rectus recommends the following ointment:

℞. Iodoformi..........................gr. 7½-15
Antipyrini
Acidi borici, āā..........................gr. 75
Vaselini ....gr. 600

M.

Wertheimer applies to burns, especially in children, the following liniment:

℞. Thymol ....gr. 1½-2
Aquæ calcis
Olei lini, āā..........................gr. 1500

M.

Starr, to allay the pain and prevent the formation of bullæ, applies instantly to a superficial burn the following ointment:

℞. Ferri perchloridi,..........................gr. 90
Vaselini ....gr. 360

M.

Haas uses an ointment made by dissolving from 150 to 300 grains of aristol in 600 grains of lanolin and the same quantity of vaselin.

Landolt and Gygax employ the following formulæ:

FOR BURNS OF THE FIRST DEGREE.

℞. Cocainæ hydrochloridi..............gr. 22½
Vaselini
Aquæ destil., āā..................gr. 150
Lanolini ....gr. 45

This ointment is said to be especially serviceable in burns of the eyelids.—*N. Y. Med. Jour.*

Some Uses of Pilocarpin.

S. Harnsberger notes some uses of this drug not mentioned in recent text-books. He cites three cases illustrating its benign effects in orchitis; it is given in 1/8-grain doses of the hydrochlorate, repeated every two to six hours, with ½-grain doses of codein, as may be necessary to produce copious sweating and relieve pain. The same drugs, in similar combination, are of great service in cholelithiasis and nephrolithiasis. In both hepatic and nephritic colic the pilocarpin is best administered subcutaneously. It deserves a trial in tonic spasm of the diaphragm in certain cases of hiccough; in cases of stricture and obstruction of the intestine when iced-poultices and wet-compresses are ill borne, codein and pilocarpin may be used with benefit. The easiest and quickest way to remove ranula is by means of one-sixth grain of pilocarpin hypodermically. —*Medical Review.*

Topical Use of Quinin in Leucorrhea.

Dr. Hardwicke speaks as follows about the topical application of quinin to the mucous membrane of the cervix uteri and vagina in cases of leucorrhea:

A patient, the mother of six children, who had been a sufferer from the above complaint for some years, having used the various remedies usually prescribed in such cases, but with only temporary benefit, her trouble sooner or later recurring, adopted the use, from prudential motives, of what proved to be quinin pessaries. Since using them not only had her leucorrhea disapeared, but her general health had improved. I have since used quinin topically, in several cases of simple leucorrhea, always with great success—in fact, I do not know of a single instance in which it has failed or in which quininism has been produced. It may be used in the form of douche or pessary. I adopt the latter form as being obviously the better one; the drug has a better chance of closer and more continuous contact with the congested membrane. I prescribe three grains of the hydrobromate in a ½-dram pessary in combination with oleum theobromatis, but the pessus quininæ of the "Extra Pharmacopeia," containing the hydrochlorid, answers just as well. One insertion a day is generally sufficient. —*Canadian Pract. and Review.*

Copper Phosphate in Tuberculosis and Chlorosis.

M. Sig. From one to four tablespoonfuls to be added to a glass of hot water, and applied locally three or four times daily. In addition, quinin sulphate with sodium bicarbonate may be administered internally.—*Brocq: Phila. Med. Jour.*

Hemostatics in Threatened Abortion.

In hemorrhage resulting from threatened abortion, the custom is, after providing the means destined to calm the uterine contractions—opium, rest, ice to the hypogastrium—to prescribe a hemostatic agent which will not provoke tetanic contractions of the organ, such as hydrastis canadensis, viburnum *prunifolium*, or hamamelis virginica. According to Professor Bossi, these agents prescribed alone are not always to be relied upon, on account of the difference of temperament so frequently witnessed in patients. Much disappointment would be obviated if these agents were prescribed together, according to the following formula:

℞. Fl. ext. hydrastis canadensis
Fl. ext. hamamelis virginica
Fl. ext. viburnum prunifolium
Tinct. piscidia erythrina, āā.................ʒii
Laudanum ....m xxx
M.

A teaspoonful of this mixture to be given every eight hours if necessary.—*Paris Cor: Med. Press and Circular.*

Whooping-Cough.

Dr. R. B. Gilbert, of Louisville, in *Practitioner and News*, says regarding the treatment of whooping-cough:

The remedies I use are not new, nor do I claim originality in their application. I may claim that I push the dosage to its full effect faster than is deemed advisable by others. The great danger to life, especially in the young infant with whooping-cough in hot weather, fully justifies the procedure.

The moment the disease is recognized I order an average dose of belladonna given once every eight hours, *the dose to be increased by one drop daily until the full physiological effect* is obtained, viz.: widely dilated pupils, flushed cheeks, dry fauces, etc., the maximum dose being reached in five or six days. The maximum dose *is continued until there is a decided* lessening of the severity of the cough, which may be confidently expected within ten days from the beginning of treatment. In addition to the belladonna, I *give, every three hours during* the night, full doses of potassium bromid combined with phenacetin, which insures prolonged, tranquil sleep, and fewer coughing spells.

For a child 1 year old I write thus:

R. Tinct. belladonnæ..........................℥i
Sig. One drop every eight hours, increasing one drop each day till the tenth day. Label bottle "No. 1."

Also:

℞. Potass. bromidi............................ʒii
Phenacetini ....gr. x
Mucil. acaciæ
Aquæ, āā................................℥i
M. ft. tal. Sig. Teaspoonful every three hours during the night. Label bottle "No. 2."—*Med. Jour.*

Simple Acne.

McKinney advocates as the remedy par excellence for simple acne, calcium sulphid. The proper dose is 1/2 grain twice daily, and this dose should be steadily *increased until four tablets* are taken each day. If the taste is objected to, it may be disguised by sugar-coating or the drug may be given in capsules. In case of excessive gastric irritation, it may be desirable to begin treatment with 1/10 or 1/5 of a grain. In the acute stages of the trouble arsenic does no good. The physician should expend a little time at each visit in gently squeezing out the larger comedones, and curetting the smaller ones with the comedone-extractor. The pustules should be lanced at the base in a slanting direction and the point of the needle or lancet swung around in the abscess cavity to break up its contents. An antiseptic can best be applied in the form of a soap containing sulphur or mercury bichlorid, with which the face can be washed at *night*.

The following are other good antiseptic preparations:

LOTION FOR ACNE.

℞. Sulphur precip..............................ʒi
Ether ....flʒiv
Alcohol ....flʒxii
M. External use.

The lotion should at first be applied only at night, but after the skin becomes accustomed to it, it may be used advantageously several times a day.

ACNE OINTMENT.

If an ointment is desired, it may be prescribed as follows:

℞. Sulphur precip.............................ʒi
Rose water ointment
Lanolin, āā................................ʒiv
M. *External* use.

Another good combination is:

℞. Potassii sulphid
Zinci sulphatis, āā..........................ʒi
Aquæ, q. s. ad.............................℥iv
M. External use.

If the skin remains discolored after the papules and pustules have subsided, an ointment of tar and sulphur or ichthyol *and sulphur should be used, rubbing it into the skin for half* an hour each night. The use of very strong stimulants, as naphthol, resorcin, caustic potash, etc., is to be avoided, as their effect is often very injurious to the skin.—*Merck's Archives.*

Salicylic Acid Administered Cutaneously.

Cullen says that Combemalle and Sigalas, of Paris, have called attention to the fact that if salicylic acid is *mixed* with some oily vehicle and applied to the skin, it may be detected in the urine in five minutes.

A favorite recipe is the following:

℞. Acidi salicylici ....ʒiiss 10
Alcoholis ....℥xiiss 50
Olei ricini............................ʒxxv 100
M. Use locally.

A tablespoonful of this mixture is poured into the palm of the hand and rubbed into the affected part for a few minutes; the part is then covered with oiled silk or rubber, and again enveloped in several thicknesses of flannel or cotton. The effect is marked. The pain disappears in a few minutes. This does not exclude the administration per os, but the drug may be given in smaller doses than usual. If the oil of wintergreen be substituted for the salicylic acid, the effect will be still better.—*Merck's Archives.*

Hydrochloric Acid in Sciatica.

Hydrochloric acid was applied over the course of the sciatic nerve or to the heels and feet, for the relief of pain in these parts in twenty-six cases. Sixteen had sciatica, which in most instances had defied every other treatment. Of these, two were completely cured, eleven were considerably relieved, and three were not improved. The remaining **patients** were
suffering from intractable pain in the heels
the sequelæ of acute rheumatism, many g
four were quite cured, one was very m
were not improved. The average number
all the cases was fifteen. The strong

Pharmacopeia was painted on the skin at bedtime, with a glass brush, in a series of lines about two or three inches long over the tender spots in the thigh and calf. When dry, the limb was enveloped in cotton-wool loosely bandaged, and so left till the morning, when the patient was allowed to get up as usual. The acid may be applied every night on the skin, but it should be discontinued directly if there is any sign of redness or irritation of the parts.—*Bayliss: British Medical Journal; Monthly Cyclopedia of Practical Medicine.*

Disorders of Puberty.

The entrance upon her reproductive life in woman is almost invariably accompanied by a certain amount of disturbance of the general health; its cessation is not rarely, if not usually, accompanied by a certain amount of erotic excitement, a period of active recrudescence of the generative instinct. Both periods commonly produce such disturbances as necessitate the calling in of medical aid. The first change, or puberty, is frequently accomplished under the cirumstances of rapid growth; and the double tax upon the system produces in many cases a distinct debility, which may lead ultimately to tuberculosis or other wasting disease. Commonly there are recurring periods of lassitude, weight, and sense of dragging in each groin, before the menstrual flow is actually established. Under these circumstances it is advisable to counsel the patient to sit over a vessel containing hot water, or, if that be not sufficient, to stay in bed and have warm cloths applied to the vulva; the last is a powerful means of exciting a flow from the genitals, and is useful not only at puberty, but at other times when the catamenia have been checked, as by cold; and it is especially useful in any arrest of the lochia. (In the last case the application of hot cloths without delay, on the arrest of the lochial discharge will often avert a grave condition.) If these measures are insufficient, it is usual to give iron with aloes.—*Fothergill: Med. Rec.*

Treatment of Pneumonia.

Latchford (*Brit. Med. Jour.*, May 5, 1900, p. 1084) reports successful results from the following mode of treatment in a number of severe cases of influenza complicated by pneumonia: During the initial congestive stage, a combination of quinin and mercury with chalk, and concurrently, fluid extract of ergot in twenty-minim doses, is regularly administered. During the second or exudative stage, when the expectoration is profuse and sanguineous, a mixture containing digitalis, tincture of ferric chlorid, quinin, and dilute hydrochloric acid is given at regular intervals. If the case is asthenic, small quantities of stimulants are also administered from time to time.

Therapeutic Applications of the X-Rays.

Schriff (*Brit. Med. Jour.*, May 5, 1900, p. 1082) refers to a case in which an extensive pigmented hairy nevus was removed by exposure to the X-rays, and also to cases of lupus vulgaris, in which similarly good results were secured by the same means. Other indications for this method of treatment are afforded by abnormal growth of hair, and all cutaneous diseases caused or prolonged by the presence of hair, such as sycosis, favus, wounds of the hairy parts of the body, nodese trichorrhexis, furunculosis, acne, lupus erythmatodes, eczema, and elephantiasis. Striking improvement takes place also as a result of the treatment when the face is disfigured by scars, pustules and comedones. The treatment should be persisted in for some time after the disease has disappeared in order to prevent recurrence. Scholefield (*loc. cit.*, p. 1083) also reports a case of lupus vulgaris of the nose, in which cure was effected by means of the X-rays.

Medicolegal.

May Waive Medical Examination.—In Watts. vs. the Equitable Mutual Life Association of Waterloo, where the latter absorbed another mutual insurance company and agreed to assume all liability on its certificates or policies, the Supreme Court of Iowa holds that a contract of reinsurance made with a member of such other company by the Association named was not void because no medical examination was made as required by the Association's by-laws, because it holds, a corporation may waive the provisions of its by-laws, and the Association must be held to have done so in this case.

Physician Carelessly Accelerating Death.—The Supreme Court of North Carolina holds erroneous an instruction to the effect that a jury can award a man no more than nominal damages where it finds that the death of his wife was only hastened or accelerated by the acts or omissions of the practicing physician and surgeon called to attend her, as, for example, in childbed sickness, and charged with carelessness and inhuman and cruel treatment accelerating her death. The error in the instruction, it points out, in the case of Gray vs. Little, is in considering the act expediting death as a mere technical injury. That, it says, is not the language of the law nor of the text-books on criminal matters. There are instances in the common law reports where the accelerator paid the severest penalty known to law. And the court says that it knows of no decision of a final appellate court in this country declaring otherwise. To this the court practically adds the suggestion that where the evidence sustains such a charge against a physician as that above stated, he may consider himself fortunate if he is not brought to trial for a high criminal offense, as well as to answer in an action for damages.

Knows Whether His Rupture is Cured.—In Wray vs. Warner, an action on a promissory note for $500, given as part payment for the right to sell a rupture cure in certain territory, where one of the defenses was that the note was without consideration, complaint was made that witnesses who had been treated with this cure were permitted to answer whether they were cured or not. It was argued that these were ignorant men, possessing no information or competency to answer the question, and that the answer was a conclusion. But the Supreme Court of Iowa sees no prejudical error in this. It says that it certainly requires no special skill or learning for a man who has been suffering from a rupture to know whether or not it has been cured; and to say that it has or has not been cured, it holds, is the statement of a fact. Moreover, the court thinks a jury warranted in finding a cure worthless, and of no value, and therefore no consideration for a note, and that the originator of the cure knew what the consideration for the note was when he took the latter, where, notwithstanding he testified to the merit and effectiveness of the cure, and that over 12,000 persons had been treated and cured with it, no one of these was called to corroborate the statement, while several persons treated with it testified that they had not been cured by the treatment.

Agreement Not to Practice Construed.—A physician, it was alleged, agreed to sell his residence house and lot in an incorporated town, and his practice as a physician, good-will, and location in said town, and was, as it was averred, to turn over and deliver to the purchaser his location, good-will, and practice in the territory surrounding said town, and was never to practice as a physician at any time in said territory. Now such contracts, the Supreme Court of North Carolina holds, Hauser vs. Harding, do not fall under the head of contracts for the restraint of trade, and are not, as such, contrary to public policy, and void. But, even so, it was argued that the contract was uncertain, both as to the time during which it was to continue and as to the territory over which it extended, and therefore void. Not exactly so, thinks the court. As to the uncertainty as to time, it says that it has heretofore held that where no time is mentioned in such contracts they are to endure during the lifetime of the grantor. Yet the language of that part of the contract which undertook to restrain the purchaser from practicing medicine outside the town mentioned, it states, was not sufficiently definite to mark and define any certain territory. Wherefore, taking the limits of the incorporated town as well defined, but the reference to territory surrounding it being too uncertain to be capable of being marked out or identified, the court holds that the seller should be enjoined and restrained during his life from practicing medicine within the corporate limits of said town, but that for uncertainty the contract could not be enforced as to the so-called surrounding territory.

Supposing Death from Violence.—Section 1221 of the Revised Statutes of Ohio provides for an inquest by the coroner whenever the death of a person, whose body has been found within the county, is supposed to have been caused by violence. In construing this, the Supreme Court of Ohio holds, State vs. Bellows, that a death "caused by violence" is a death caused by *unlawful means*, such as usually call for the punishment of those who employ them. A body "is found" within the county when it is ascertained by any means that it is within the county. "Death is supposed to have been caused by violence" whenever from such observation as he may be able to make, and from such information as may come to him, the coroner is, for reasons of substance, led to surmise or think the death has been so caused. In this view, it holds that it is the duty of the coroner to hold an inquest, and to perform the other duties enjoined upon him in this connection, whenever a dead body is found within his county, and he knows or may reasonably believe that death was caused by unlawful means. To hold that, within the contemplation of the statute, death can not be supposed "to have been caused by violence" if persons other than the coroner may know that it was so caused, the court thinks, would defeat the purpose of the statute, since murderers and their accomplices always know that the deaths of their victims were so caused. On the other hand, Mr. Justice Davis maintains, in a dissenting opinion, that the statute does not authorize a coroner to hold an inquest when the death is not "supposed" to result from violence, but is known to be the result of a murderous assault openly perpetrated in the presence of a number of persons. He insists that the coroner can not take the place of a prosecuting attorney, examining court, or grand jury, under the pretext of an inquest.

Private Not "Charitable Institutions."—All must admit, says the Court of Appeals of New York, that the term "charitable institution" does not include every corporation or society that has some charitable feature or is engaged in some good work, but that its meaning must be limited. Assuming this proposition to be beyond dispute, the court seeks to determine, in the case of People ex. rel. State Board of Charities vs. the New York Society for the Prevention of Cruelty to Children, where the line is to be drawn. In other words, it had in this case to settle the construction to be put upon this term as used in the state constitution, and, based upon the latter, in the statute creating and conferring on the state board of charities the right of visitation and inspection of all "charitable institutions." As a result, it holds, denying a motion for reargument, that a charitable institution must be one that in some form or to some extent receives public money for the support and maintenance of indigent persons. By "public money" it means money raised by taxation, not only in the state at large, but in any city, county, or town. The adoption of this principle, it says, will permit the board to visit, inspect, and regulate every institution in the state, public or private, where children or adults are supported or maintained, in whole or in part, by the use of public money, and every institution, public or private, where children or adults are sent or detained for support or maintenance in pursuance of any law. And it declares it not very easy to see how the state can examine into the evils or correct the abuses in a purely private unincorporated institution, to which no one could be sent, or in which no one can be detained, by any law, and where the inmates may come and go at pleasure. Suppose that a private individual is wealthy and benevolent enough to found and endow a private hospital. When complete, the building and everything in it is his private property. No one is compelled by any law to go there or remain there, and the founder is under no legal obligation to receive patients. It is purely a private concern, and it is difficult, the court insists, to understand upon what legal ground the state can claim the right to inspect his books, or to make rules and regulations for the transaction of the business. There must be some limit to the power of government to interfere in purely private affairs, and what is true of a hospital is equally true of many other private institutions. But when any of these institutions become, in any form or to any extent, the recipients or beneficiaries of public money, as charity, there is a just and reasonable ground upon which the state may claim the right of visitation. And it thinks that it is safe for the courts to assume that private institutions, or such as admit or care for children or adults without any compensation from the public, and where the inmates are in the institution solely by their own volition, depending on the patronage of the public, will be interested to merit it by such a management of their affairs as will commend them to the confidence of their patrons, and that, if they fail to treat the inmates properly, they will not go there voluntarily, or remain when there. If they are detained there against their will, the process of the courts is open to them to secure their enlargement or liberation. In short, the court thinks that the perfect liberty of action which the inmates enjoy, and the promptings of self-interest on both sides, will regulate private charity without any governmental interference.

The Kentucky Decision on Osteopathy.—The decision of the Court of Appeals of Kentucky, in Nelson vs. State Board of Health, is very largely one of statutory construction. First, the statute regulating the practice of medicine in that state requires the State Board of Health to issue a certificate to any reputable physician having a diploma from a reputable medical college, without any discrimination against any peculiar school or system of medicine. The term "physician," as used therein, the court holds, refers to those exercising the calling of treating the sick by medical agencies, as commonly practiced throughout the state at the time the act was passed. The term "medical college" refers to those schools of learning teaching medicine in its different branches, at which physicians at that time were educated, or schools of that character organized since. At such an institution an essential part of the instruction was in teaching the nature and effects of medicines, how to compound and administer them, and for what maladies they were to be used. Surgery was also an essential part of the instruction. But osteopathy teaches neither therapeutics, materia medica, nor surgery. Bacteriology is also ignored by it. Hence, the court holds that a school of osteopathy which teaches neither of these branches can not be regarded as a reputable medical college, within the meaning of the statute. The title of this act is, "An act to protect citizens of this commonwealth from empiricism." The act, the court therefore holds, is "an act to protect the people of this commonwealth from the practice of medicine founded on mere experience, without the aid of science, or a knowledge of principles." And as the board is only authorized to issue a certificate to a reputable physician having a diploma from a reputable medical college, and no discrimination is allowed against any peculiar school or system of medicine, the court holds that the penalties provided by the last section of the act must be limited to that which is referred to in the title and previous sections—the practice of medicine in some of its branches in this state (Kentucky); and the words, "who shall practice medicine or attempt to treat any sick or afflicted person by any system or method whatsoever, for reward or compensation, without first complying with the provisions of this law," must be held to refer to physicians or surgeons belonging to some school or system of medicine practicing or desiring to practice medicine in Kentucky, *as provided in the preceding section*. In other words, taking the statute as a whole, the court does not think that it was designed to do more than regulate the practice of medicine by physicians and surgeons, while an osteopath, it holds, is in no proper sense a physician or surgeon, and does not practice medicine. He is rather, it holds, on the plane of a trained nurse. Services in kneading and manipulating the body, it says, are no more the practice of medicine than services in bathing a patient to allay his fever or the inflammation of a wound. And if by kneading and manipulating the body of the patient he can give relief from suffering, it sees no reasons why he should not be paid for his labor as other laborers. So it holds that so long as he confines himself to osteopathy, kneading and manipulating the body, without the use of medicine or surgical appliances, he violates no law, in Kentucky, and the State Board of Health should not molest him. But, it at the same time declares, he may not prescribe or administer medicine or perform surgery.

THE JOURNAL OF THE
AMERICAN MEDICAL ASSOCIATION.
61 MARKET STREET, - CHICAGO.

SATURDAY, JULY 21, 1900.

THE PATHOLOGY OF FIBRINOUS BRONCHITIS.

Fibrinous casts are formed in the bronchial tubes under several conditions, such as the presence of diphtheria and pneumonia, and blood-casts may appear in connection with hemoptysis; but apart from these, there occurs an independent disorder, in which bronchial casts are expelled in paroxysms attended with dyspnea and cough. Of this last-named condition, the etiology and the pathology are obscure. The disorder is generally chronic and characterized by recurring paroxysms. Opinions differ as to the nature of the casts expelled, which are believed by some to be really fibrinous, and by others mucinous. It has also been suggested that the bronchial casts result from chylous exudation, but this view has not received acceptance. A case presenting several interesting features was demonstrated a short time ago by Strauss[1] at a meeting of the Association of Charité Physicians at Berlin. The patient was a man, 58 years old, with a history of syphilis, who, two months before coming under observation, was seized with shooting pain, and a sense of pressure in the chest and the epigastrium, together with cough and dyspepsia. The cough was aggravated in paroxysms, in which inspiration was not embarrassed or attended with wheezing. These spasmodic attacks of cough were associated with the expectoration of thick, viscid mucus, containing tough grayish-yellow filaments, which were found to be tubular in structure, dividing dichotomously, and containing numerous Charcot-Leyden crystals. The chest was enlarged, the percussion-note resonant, the respiratory murmur vesicular, with numerous sibilant and sonorous râles. The sputum contained no tubercle bacilli, the urine, neither albumin nor sugar, and examination of the nose disclosed no abnormity. Except for arteriosclerosis, the circulatory system also exhibited no enormity. The attacks occurred principally at night, and especially toward morning, and were lacking in the characteristic features of bronchial asthma. Inspiratory wheezing was absent, and dyspepsia and cough were present in the intervals between the attacks. The usual therapeutic measures were without noteworthy influence, but the expectoration of coagula ceased in the sequence of a febrile attack of influenza, although Charcot-Leyden crystals persisted in the sputa. A diagnosis of fibrinous bronchitis was made on account of the absence of typical attacks of bronchial asthma, and of the occurrence of paroxysms of cough limited to the expiratory phase of respiration. The size of the casts, also, seemed to favor this diagnosis, although casts of large bronchi are occasionally expectorated in cases of asthma. While Charcot-Leyden crystals are most commonly observed in the sputum in cases of asthma, they have also been observed in cases of fibrinous bronchitis.

The differential diagnosis between fibrinous bronchitis and bronchial asthma would be easier if the casts expectorated could be distinguished chemically, but this can not be done, and in cases of each disease they sometimes consist of fibrin, and at other times of mucin. In the present case the coagula were hollow and laminated, and yielded the reactions of fibrin. As, however, it appears that mucinous coagula are capable of inducing similar attacks, the chemical character of the exudate would seem to be less important than the mechanical obstruction of the branches of the bronchial tree. It was found, further, that the Charcot-Leyden crystals took the same stain as the fibrin. Mononuclear leucocytes predominated in the casts, and 20 per cent. of the leucocytes in the sputum were eosinophile cells. The number of esinophile cells in the blood, however, was not increased. Among the various cocci present were diplococci resembling pneumococci.

Schittenhelm[2] reports two carefully studied cases of fibrinous bronchitis, with the post-mortem findings in one that terminated fatally. In these, as well as in a considerable number collected from literature, it was found that the physical signs indicated a localization of the morbid process in certain portions of the lungs, always the lower lobes, and its reappearing with the formation of the casts. The rapid onset, and the equally rapid subsidence of the physical signs after expectoration of the coagula, were noteworthy in several cases, together with the cyanosis and the sudden development and the rapid progress of the dyspnea, immediately ceasing with the expectoration. The coagula yielded the reactions of fibrin. In the case studied post-mortem, evidences were found of desquamative catarrh of the alveoli, together with exudation into the bronchi, the bronchioles, and the alveoli.

A PLEA FOR CONCISENESS IN WRITING.

In a recent issue of *Virchow's Archiv* there appeared a communication from its venerable editor asking contributors for greater condensation and conciseness in their writing, and pointing out how, from an editor's point of view, German medical literature could be improved in substance and in style. Virchow deprecated especially the useless fullness of clinical and post-mortem details, the tendency to make elaborate tabulations where comprehensive statements would be better, and the space given to useless and generally very incomplete résumés of the literature, often at second and third hand, but quoted as from the original sources, thus lowering the moral tone of the article. "How often," he says, "is valuable space taken up by piling up citations that the author has never thought it necessary to verify." He emphasizes the need of greater condensation and limitation of space to what is actual and, if possible, new, to restore German medical literature to the old standing. The editor of the *Deutsche Medicinische Wochenschrift* reproduces the larger part of the editorial, and modestly says that—*si parva licet componere magnis*—he also would like to express his "long-suppressed but profoundly felt irritation" on account of this condition of affairs. The reputation for thorough work of German medical literature, it thus appears, has come to hide a multitude of sins some of us have more or less appreciated, but which are here set forth by one whose words carry more weight in this matter than those of any other of his countrymen. The insufficiencies of the references in German medical papers to American contributions have been very obvious to every one, but the charges contained in Professor Virchow's editorial will come as a sort of shock to the reverence for everything German that is so widespread in this country.

---

[1] Berliner Klin. Woch., 1900, No. 19, p. 407.

[2] Deutsches Archiv f. Klin. Med., Bd. lxvii, H. 3 u. 4, p. 336.

For purposes of general information it is well sometimes to know of others' faults as well as our own, although there is no special reason for self-congratulation in this country on account of this fact. Here we stand between two evils, as far as medical literature is concerned: on the one hand the exceedingly superficial, and on the other the sciolistic and pedantic following of the bad German model above reprobated. The overburdened clinical descriptions, elaborate tabulations and the immoral second and third hand references purporting to be from the original text, can all be found in some articles published in this country. The reform needed in Germany is needed here also, and the tendency to make medicine, like law, a study of precedents and citations of authorities, sometimes without rhyme or reason, also needs a check. American as well as other medical writers should learn that there is ability shown in condensation and concise statements as to what is new or valuable as deduced from known facts or new facts presented. Two-thirds of the American medical literature is not especially valuable, and it is small consolation that the same is the case in Germany, which some look to as a model in this respect. We need not go so far as Professor Virchow when he says that he will refuse all articles of more than three forms in length, but we can certainly say we sympathize with him from the editorial standpoint as well as from that of a reader. There is, perhaps, less in Germany of what might be called graduation thesis literature, made up of long-known facts and possessing nothing new, than in this country; there may be a few more cases recorded and a show of experimental study and work, but we are all made of the same flesh and share the same faults. There is room for improvement here, as we have long been aware, but would not of ourselves have thought of taking Germany's deficiencies as a text had it not been so aptly furnished us.

THE CURE OF TABES DORSALIS.

In the records of quacks, as well as in the minds of neurologists at large, there is a wide margin devoted to the uncertainties of the diagnosis of locomotor ataxia. Many of the former class wax wealthy on the reputations, honestly acquired, of a single case, pronounced locomotor ataxia by the ablest nervous experts, and many patients pursue the phantom of beef and hot water which has been incident to the getting well of certain cases pronounced incurable by the specialist. The neurologist is sometimes treated to the shock of finding such a cure in one of his formerly classified incurable cases, and immediately goes over his notes to find out where he made his blunder. In the light of our present knowledge there would seem to be no doubt—and this is recognized in our text-books—that there exists a form of neuritis, often of alcoholic origin, which gives rise to many of the typical symptoms of locomotor ataxia. It is in this category that the charlatan reaps his harvest and the neurologist his mortification.

We are indebted to Leyden for the first accurate and thorough portrayal of the picture of polyneuritis, from a clinical as well as from a pathological standpoint. Before his time it was the fashion to follow Charcot's dictum, laid down in 1880, that atrophic paralyses were always associated with changes in the ganglion-cells of the anterior horns, and it was reserved for Eichhorst, Joffroy and Eisenlohr to demonstrate that such muscular conditions might arise and yet the anatomical changes in the spinal cord be wanting. But it was Leyden's critical instinct that enabled him to make a distinction between the symptom-complex of a polyneuritis and an anterior polymelitis, with which latter affection the former was so persistently associated in the minds of the neurologists. At the present time there is little ground for confusing these pathological entities.

In a recent paper, v. Hőnig[1] outlines the history of the development of our knowledge bearing on the subject of polyneuritis, and considers in particular the ataxic form of alcoholic polyneuritis. He believes that from a clinical point of view etiological classification is the most satisfactory one, and distinguishes, as do most modern writers, three types of polyneuritis: Primary polyneuritis, having its origin from exposure to cold or from overstrain; secondary polyneuritis, following many of the infectious diseases, and toxic polyneuritis from lead, arsenic, mercury, alcohol, etc. There is no doubt that of these alcohol plays the most important rôle. Of the different types of alcoholic polyneuritis Hönig characterizes three, motor, sensory and ataxic, the first being characterized by paralytic phenomena, the second by modification of the sense organs, and the third typified by marked inco-ordination of the voluntary movements of arms and legs. With reference to the frequency of occurrence of these, statistics indicate that the paralytic form is the most common; the sensory type the least, and the ataxic type occupies a middle ground.

The author's search through literature—and from
bibliographical references, it must have
perficial research, since hardly any
American writers, notably Dan

---

[1] Deutsches Archiv f. Klin. Med., vol. lxvii,

collect reports of forty cases of ataxic alcoholic polyneuritis or false tabes. In most of these, all the extremities were more or less involved; in many, although not all, the symptoms developed with rapidity; Romberg's symptom was present, and in all save two the patellar reflex was abolished. One symptom—diminished or absent light reflex associated with the accommodation reflex, the Argyll-Robertson pupil—was noted to obtain in three cases. This symptom has been held to be absolutely differential in the diagnosis of tabes, and it is of import to note its presence in three of these patients with neuritic tabes—all of whom recovered. Other signs present in tabes, such as the girdle sensation, double vision, and the disturbances of the bladder, were uniformly absent. A symptom considered of almost pathognomonic importance was the occurrence of the reaction of degeneration in some of the affected muscles; this, with the absence of the bizarre sensory changes of tabes, should always be borne in mind in the diagnosis of these cases.

In the matter of treatment, much stress is put upon the action of strychnin. This alkaloid, in the hands of the author, given in very large doses, has been of much value in the treatment of this condition, and the reports of the cured cases in literature seem to point much in the same direction.

The contribution is timely, and the caution, that exact diagnosis of this alcoholic pseudo-tabes would deprive the charlatan of his much-vaunted superiority in the cure of locomotor ataxia, is worthy of consideration.

MEDICAL DEPARTMENTS OF STATE UNIVERSITIES.

Not a few of our state universities have more or less prosperous departments of medicine, as for instance, the Universities of Michigan, Minnesota and Iowa. The number of medical students in these and other institutions of similar character is large; in some cases undoubtedly larger than the facilities for proper clinical instruction warrant, so that actual overcrowding has resulted. Difficulties in securing sufficient material for adequate clinical teaching of the large classes have arisen from time to time. Gradually these shortcomings are being more or less satisfactorily met by the erection of state or university hospitals under the management of the medical faculties.

Undoubtedly, one potent reason for the large number of students in many medical schools of this character is the relatively small fees demanded. Presumably on the theory that the state should furnish its citizens with opportunities to secure medical education at as reasonable cost as possible, the medical fees have been kept at comparatively low figures. At the same time the requirements for entrance and for graduation have not, as a rule, been higher in the medical departments of state universities than in schools without state support. We doubt whether it may be claimed with justice that the state universities have taken a conspicuous lead in the gradual advancement in the requirements for entering the profession of medicine, that is such a conspicuous and gratifying feature in the recent medical history of this country. We do not wish to discuss at this time the advisability of the state giving its citizens fairly good opportunities for acquiring professional knowledge at small cost. There is much to be said both for and against this policy. But it is surely not unreasonable to look to the state universities to take an active and decided lead in bringing to a high standard the requirements for entering medical study and the quality of education given.

The medical departments of state universities surely ought to be wholly independent of the number of students in attendance upon their courses. Numbers and commercialism should not have a decisive influence upon the general educational policy of a state university. Numbers are wholly unnecessary in order to have state medical schools. They are unnecessary in order to have a university in the true sense. Excessive numbers of students seriously hamper the real work of all schools so afflicted. It may be a potent argument with parsimonious legislators and regents to point to continued increase in the number of students in the professional schools of a state university when asking for increased appropriations—in fact, it may be the only argument that will carry the necessary weight with men enslaved by the commercial spirit of our times. In the true interests of medical education, however, it is hoped that the governing bodies of state universities may yield to better reasons than the argument of numbers when it comes to the setting aside of public money for the proper building up of medical and other professional departments; and the more so when it is recalled that the increasing number of students not infrequently largely depends upon insignificant fees and liberal, not to say mediocre, requirements for entrance and for graduation.

DANGERS FROM THE USE OF PROPRIETARY REMEDIES.

In an admirable address on "Progress in Therapeutics," delivered recently before the Philadelphia County Medical Society, Dr. S. Solis-Cohen dwelt on "the great flood of proprietary remedies, secret or half secret, that has been let loose upon the profession and the public," as one of the dangers arising from the great power over symptoms residing in modern synthetic remedies and from the great improvements constantly being made in the art of pharmacy. "The practitioner who is lazily contented to give the mixture exploited by some manufacturing firm, rather than to use his own brains to find a remedy or a combination of remedies suitable for the case of the individual patient loses the faculty of selecting or combining remedies. In so far as these remedies are secret nostrums, they threaten to destroy all therapeutic science; for ignorance, which is the aim of secrecy, is the very antithesis of science. The physician who uses an alleged remedy of the composition of which he is ignorant can have no scientific basis for his action, can add nothing to his own knowledge for guidance in future cases, can add nothing to the general store of knowledge of the profession."

MARRIAGES BETWEEN INDIVIDUALS OF THE SAME SEX.

As a rule, there is no difficulty in determining the sex of an infant, while, as growth and development progress, even such doubt as may arise in rare instances is gradually dispelled. Nevertheless cases have been recorded in which individuals of the same sex, or at least of doubtful sex, have entered upon the marital relation. In recent numbers of the *Revue de Gynécologie et de Chirurgie Abdominale,* Neugebauer publishes the notes of 53 cases of marriage between persons of the same sex, collected from various sources, together with 11 in which marriage-engagements were broken off on discovering that an error in the sex of one or the other of the contracting parties had been committed, and 15 in which individuals leading the lives of prostitutes were found to be of the male sex. In two instances the victims of the mistake committed suicide. Among the 53 cases of marriages 49 men had passed as women and 3 women as men, while one of the individuals was said to have been a hermaphrodite. Most of the cases are probably instances of peno-scrotal hypospadias. The question is an important one, both from the medicolegal and the sociological standpoint, and great care should be exercised in reaching a decision, and this at as early a period as possible.

COMPULSORY VACCINATION OF CHILDREN IN PUBLIC SCHOOLS DECLARED LEGAL IN PENNSYLVANIA.

An important decision as to the legality of compulsory vaccination of school-children in Pennsylvania has just been rendered after a month's advisement by President Judge Pennypacker and Judge Sulzberger in the Court of Common Pleas in the City of Philadelphia. In order to test the question whether or not children must be vaccinated before entering the public schools, a citizen had brought a mandamus proceeding against the principal of one of the schools to compel the admission of his daughter, who had never been vaccinated, as a pupil. The respondent filed a return, in which she averred that she was required to refuse admittance under the rules of the Board of Education and an Act of Assembly, both of which require the vaccination of children prior to admission to the public schools. To this a demurrer was filed, alleging its insufficiency at law. After argument, in which the merits of vaccination and the right of the Legislature and of the Board of Education to make such a regulation as the one in question were discussed at length, a decision was rendered overruling the demurrer and entering judgment for the defendant. While to an open and unprejudiced mind there can be no room for any other opinion, the decision just rendered is a most important one, and it should have a widespread and salutary influence. It not only concedes to the State and to boards of education the authority of protecting those who have been entrusted to their care from a virulent and loathsome disease, now almost entirely eradicated, by means of one of the most beneficent discoveries ever conferred upon mankind; but, more than this, it again stamps with deliberate judicial approval the preventive practice of vaccination.

PERIODIC EXAMINATIONS AND MEDICAL PRESCIENCE.

Dr. Gould's article in this issue pleading for the collection and preservation of accurate medical data—a more complete form of vital statistics—is one that will bear consideration on the part of the profession. The tendency of specialism to consider the patient only in connection with his particular disease, and not as a diseased individual, is, to a certain extent, not a factor for progress; there is, as he suggests, a danger of our losing the co-ordinating sense and oversight of the organism as a whole. The old-fashioned country practitioner, if adapted to his work, was, and still is, within his limits, a nearer approach to the ideal, as Oliver Wendell Holmes in one of his books has so happily described. He works largely by rule of thumb; the instruments of precision in diagnosis may be to a great extent ignored, but he learns to know his patients, their condition, their strength and their weakness, their heredity, the local causes of disease, and so on to the end. Of course this is not accurately tabulated knowledge, but it is equally useful; there may be a possible danger of becoming too dependent on formulated statements and instrumental tests. If we could only generalize the experience of the family doctor with all the aids that science can supply, we might reach that point of scientific prescience in medicine that Dr. Gould makes his ideal. And to do this we have, after all, at our command only the general methods he has pointed out.

SUITS FOR DAMAGES AGAINST PHYSICIANS.

One of the dangers to which medical men are exposed in the performance of their duties is illustrated by a recital in *The Lancet*[1] of the case of two physicians who were sued for false imprisonment by a coachman presenting symptoms of suicidal mania, to whose insanity they had, after careful investigation, certified, and who, in consequence, was detained in the lunacy-ward of a workhouse-infirmary. Recovery soon took place, and the man was discharged, cured. The jury rendered a verdict in favor of the defendants, but apart from the annoyance and the inconvenience attendant upon the suit, they were subjected to a great expense—about one hundred pounds—in their defense. In another case, also related in the same number of *The Lancet,* damages of one hundred pounds were assessed against a medical practitioner for libel in writing to a relieving officer, certifying to the insanity of a woman who had passed examination for certification as a dispenser, and who, therefore, would be dangerous to the community in which she pursued her profession. According to the evidence, the woman suffered from hallucinations, and there could be no reasonable doubt in intelligent minds as to her mental condition. While it is true that the rights of the community can not be too jealously safeguarded, it is likewise true that it is far too easy to sue for, and not rarely to secure, damages against medical men who are acting wholly and strictly within the line of their duty.

CARBOLIC ACID GANGRENE.

That carbolic acid, applied externally in weak solutions, may cause gangrene of parts of extremities has been known for something like thirty years, but unfortunately this knowledge is not general, either among the lay or medical public. Harrington's article[1] on this subject is therefore a timely and also a valuable one. The cases he reports, added to those recorded in the literature, make a total of 132 examples; and Harrington thinks it probable that many hundreds of fingers have been destroyed from this cause. The popularization of carbolic acid as a household remedy for the treatment of small wounds and bruises is undoubtedly largely responsible for many such results, but in not a few cases the treatment has been instituted at the suggestion of physicians, and, we doubt not, by the advice of druggists as well. "An aqueous solution of carbolic acid (1 to 5 per cent.), if applied to an extremity, as the fingers or toes, for a number of hours, in the form of a moist dressing or poultice, may produce gangrene or total destruction of the part." This may result without the effect of compression, merely from wrapping a cloth wet with the solution around the member. The length of the application need not exceed 12 to 24 hours, if the cloth is kept moist during this time. The explanation of this untoward result is not clear. It has been suggested that the gangrene results from the action of the acid upon the nerves of the part; from the production of thrombosis and prevention of nutrition; from direct chemical action on all parts of the tissues. Lévai—cited by Harrington—showed that dilute solutions of other acids and of alkalies—hydrochloric, nitric, sulphuric, acetic and caustic potash—may have the same effect when similarly applied. It is plain that the public, including druggists, should be taught to use other substitutes for wet dressings for trivial injuries. Harrington suggests tincture of hamamelis or solutions of borax or boracic acid. The fact that gangrene does not always result from the application of carbolic acid makes this agent the more dangerous.

THE LYMPH-NODES IN BUBONIC PLAGUE.

It is proper that our pathologists and physicians should study the various problems in connection with a disease like bubonic plague, even though an invasion by this terrible scourge may seem to some afar off. As shown by the recent experiences in New York and in San Francisco, there is no telling the day when the grim specter may stare us directly in the face; and at such times it is of the greatest importance to have close at hand men who are personally familiar with the various aspects of the disease, and its powerful bacillus—men in whose opinion and judgment we may place full confidence. That scientific work of this kind is being carried on is shown by the recent communications to the Pathological Society of Philadelphia. At the meetings of April 12, and May 24, 1900,[1] papers were read, by McFarland, on "The Bacillus of Bubonic Plague," and by Harris, on "Pathologic Alterations of the Lymph-Nodes in Bubonic Plague." McFarland's paper gives the principal characteristics of the plague bacillus, based upon personal study of this dreaded organism. Harris describes the changes in the lymph-nodes produced by the disease. In about one-half of the cases the inguinal glands are first affected; of the remaining half about 50 per cent. first show enlargement of the axillary glands. In a short time the other lymph-nodes become swollen and hemorrhagic, especially those in the pharynx, intestines, and mesentery. The glands principally involved may at first be hard, but in violent cases they soon become soft, often showing a mucilaginous or lard-like center. The dilated vessels contain many bacilli; in advanced cases the normal structures are converted into a granular material containing among the cellular debris "countless myriads" of bacilli. Hyalin phagocytic cells containing thirty to forty bacilli are present. Numerous basophile cells—mast cells—are also found, and Harris traces these cells to changes in the hyalin cells just mentioned. The mast cells are not phagocytic; they are surrounded, however, by a zone that is free from bacilli, suggesting the setting free of an antitoxin. In fact, the number of mast cells is so marked as to be of much diagnostic importance, according to Harris. In view of these results it is hardly correct to speak of the uncomplicated bubo of pest as suppurating.

"MARCHAND'S ADRENALS"—A NEW MAMMALIAN ORGAN.

In an extensive article upon the comparative embryology of the adrenals, Otto Aichel[1] considers at some length the so-called accessory adrenals in man—their location, frequency, structure and origin. He places the accessory adrenal masses occasionally found in the immediate neighborhood of the adrenals in the same relation to the main organs as accessory spleens and accessory pancreas, namely, as the result of separation of small pieces from the main organs. The adrenal structures that occur in the broad ligaments of women and in the neighborhood of the testicle and the spermatic cord in men, he regards, however, as having an entirely different significance. These structures are of so constant occurrence that they may be regarded as normal organs and ranked with mammalian organs in general. Having been first described by Marchand, Aichel suggests for them the name, "Marchand's adrenals," in order to distinguish them from the ordinary accessory or misplaced adrenals only occasionally present near the adrenals proper, suprarenal capsules. "Marchand's adrenals" are situated a little inside the free margin of the broad ligament in woman, and in man in the neighborhood of the spermatic cord between the testicle and the epididymis. Aichel found them in the broad ligament of every woman examined; generally, however, they are so small as to require uninterrupted serial sections for the successful demonstration of their presence. In man they are generally detected with the naked eye; Schmorl found them in 92 per cent. of the cases in which he looked for them. These organs are said to be constant in animals also. They can not therefore be regarded as accidental, pathological findings. Aichel derives their origin from the transverse tubules of the epoophoron, and he thus gives them an origin independent of that of the suprarenal capsules, to which they correspond histologically. Whether "Marchand's adrenals" are of functional importance remains to be learned. Removal of the suprarenal capsules in animals has been shown to be followed by their enlargement, generally regarded as of compensatory nature. In man it would be well to study these minute structures in Addison's disease, in which we are accustomed to find the main adrenals the seat of destructive lesions.

TUBERCULOSIS AND PHYSICAL DEGENERACY.

The question as to the heredity of tuberculosis, in the strict sense of the term, may be considered as fairly settled; it is hereditary only in the very exceptional cases in which the direct transmission of the germ takes place in antenatal life. It is equally well established, however, that there is a tendency to weakness that makes its bearer especially susceptible to the infection of this disease, and that this heredity is often observed in those whose direct ancestors have been its victims. The popular notion, therefore, of the heredity of tuberculosis has a rational origin, and, using the term in a wider sense than is literally scientific, may be said to have its basis in fact. It is, however, not the descendants of the tuberculous only that possess this heredity; the degenerative tendency may start in other diseased conditions, just as tuberculosis itself may give rise to special weakness toward other and not apparently related affections. It is the depraved constitutional tendency with which we have to deal, and not its particular cause. The tendency of modern studies of tuberculosis seems to be to show that its malignancy largely depends upon extraneous conditions, and that to a large extent it is a curable disease. Indeed facts are developing all the time that point to a very general infection of our species, and a spontaneous cure, so to speak, in by far the large proportion of cases. The researches of Naegeli we recently noticed[1] are most striking, as they seem to show that healed or latent tuberculosis is almost universal in adults. The germ makes its way into the system, but is unable to complete its mischief in the vast majority of cases. Whether or not we accept such a condition as generally true, it can not be denied that the infection is by no means the fatal one that it is often assumed to be, and the question naturally arises: Are we to attribute the first importance to the resisting powers of the human organism or to the virulence of the infection? Dr. Charles Denison, in our columns last week, emphasized the first of these alternatives; the necessity of attention to the soil and not too exclusively to the seed. The chances of tubercle infection are well-nigh universal, and while it may be well to give our attention to its prevention, it must not be at the expense of other matters even more important. These last, the proper care of the health of the predisposed, the hygiene of the masses, as well as of the pulmonary cripples, are the weightier matters of the law, and, as he holds, the real strategic points in our combat with tuberculosis. That he is in a large measure correct is proved by the sanatorium treatment, which shows that under proper conditions the disease can be checked or cured in any climate, provided abundance of fresh air, scientific hygiene and rational medical treatment for the general conditions and symptoms are secured. It is well to keep this aspect in view, as the tendency is, perhaps, at present to dwell too exclusively on the almost impossible task of eradicating the ubiquitous germ.

HYDRIATRICS IN THE PROPHYLAXIS AND TREATMENT OF PULMONARY TUBERCULOSIS.

The use of water as a therapeutic agent is probably not as general as it should be, and it would appear that this measure would be especially indicated in cases of chronic disease attended with impaired nutrition and wasting. The problem in the treatment of tuberculosis is essentially one of nutrition. While the tubercle bacillus is the exciting cause, the conditions must be rendered favorable for its invasion and multiplication. The prophylaxis will, therefore, consist principally in measures directed toward rendering the conditions unfavorable, and the treatment should have the same aim. To this end it is believed that hydriatric measures, intelligently employed, are capable of materially contributing. They find an ardent advocate in this connection, in Professor Winternitz, of the University of Vienna, who has had an enormous experience in this field of therapeutics, and who discusses (*Berliner Klinische Wochenschrift*, 1900, No. 18, p. 384) some of the indications for, and the rationale of, their employment. He points out that tuberculosis does not develop suddenly. Deficient innervation, impaired circulation, various nutritional disturbances, especially gastric and intestinal disorders, anemia, etc., predispose to its occurrence, and every agency that antagonizes these conditions possesses prophylactic value. Ordinary cold water acts as a powerful tonic, improving the appetite, increasing the weight, enriching the blood, augmenting muscular power, stimulating innervation, and accelerating metabolism. It antagonizes retrogressive and favors constructive metamorphosis. It fortifies the body against the undesirable effects of cold. The systematic training of the sensory peripheral nerve-terminations and of the vasomotor nerves overcomes the great susceptibility on the part of the tuberculous patient to catarrhal affections. Cold water exerts a beneficial influence upon the local morbid process in the lungs, inducing increased activity in the flow of the blood to and from these parts, and improving the circulatory conditions generally. These results are brought about by invigorating the action of the heart, improving the tone of the vessels and the tissues, inducing collateral or active hyperemia in the affected organs, and strengthening the entire organism, particularly innervation and circulation. Hemoptysis, hectic fever, and night-sweats are also favorably influenced by hydrotherapeutic measures. The plan of procedure pursued by Winternitz is directed to securing prompt and complete reaction from temperature as low as can be borne, in conjunction with appropriate mechanical and chemical irritation. Stimulating affusions are also applied over the diseased parts, and thermic and mechanical symptomatic treatment is directed toward the fever, the night-sweats, hemoptysis, and cardiac and circulatory manifestations.

The Danish Government has appropriated 400 kroner for the expenses of the delegates to the International Medical Congress.

---

[1] The Journal, June 30, p. 1672.

Medical News.

Dr. Max Nordau will visit America soon.

The American hospital ship *Maine* has sailed for China, for the purpose of caring for the wounded among the Americans and English.

The centenary of the Royal College of Surgeons of England will be celebrated on July 25 and 26. There will be a conversazione at the college on the first day, and on the second a meeting in the theater of the University of London and a banquet in the hall at Lincoln's Inn.

A hospital for children has recently been opened in Athens. It is called "Saint Sophia," in honor of Princess Sophia of Greece, and was opened in the presence of the royal family and the high officers of the state and city. There are twelve buildings, four of which are isolated for contagious diseases.

The students of Paris have organized a series of fetes in honor of visiting students, August 5 to 12. The mornings will be reserved for the Students' Congress, the afternoons for visits to the exposition in groups, and the evenings for the theaters. The minister of public instruction and the president of the *Association générale des étudiants* will preside at the general meeting at the Sorbonne the first day.

The Plague.—During the week ending June 2, 746 deaths were reported in India from the plague, as compared with 975 in the previous week. In Bombay, 205 deaths occurred, and in Calcutta, 167. In Rio Janeiro, there were 27 cases and 13 deaths during the first week of June. The Propaganda at Rome has received intelligence that the plague is spreading with alarming rapidity in Pekin, and that early in June, four Italian missionaries had died from the disease.

Physicians in China.—A list has been published of the Americans in China from whom no word has been received and who either have been murdered or are in grave peril. The list includes the following four physicians: John M. Inglis, Pekin; Cortlandt Van Rensselaer Hodge, Maud A. Mackey and G. Yardley Taylor, Pao-Ting-Fu. Six physicians in China are reported to be safe, namely, Charles Lewis and Edna B. Parks, Sinan-Fu; W. R. Faries, Wei-Hein; C. F. Johnson and Miss E. E. Fleming, Ichow-Fu; and Edna U. Terry, Tien-Tsin.

PENNSYLVANIA.

Two deaths from lockjaw, resulting from injuries on July 4, have so far been reported; one in Altoona and the other in Philadelphia.

BOARD OF HEALTH.

The forty-sixth regular meeting of the State Board of Health was held at Mt. Gretna, July 12. The secretary, Dr. Benjamin Lee, made his report, expressing appreciation of the Philadelphia Board of Health in authorizing the physician in charge of the Municipal Hospital to give instructions to students attending the medical colleges there. It was found that some of the water-supply of Philadelphia was contaminated at Norristown. Dr. Samuel T. Davis, Lancaster, was elected president of the Board.

DISEASES AMONG CATTLE.

At the last meeting of the State Live Stock Sanitary Board, held at Harrisburg, July 8, Dr. Leonard Pearson, state veterinarian, stated that, during the past month, 31 tuberculous cattle were condemned. Blackleg was reported from a farm in Franklin County, and also from a farm in Somerset County. Anthrax was found in a herd at Kennett Square and also in Jefferson County. Most of the cattle exposed to the disease have been rendered immune. A large number of suspected outbreaks of contagious diseases were reported, but on examination it was generally found to be due to other causes.

MEDICAL DEPARTMENT, PENNSYLVANIA NATIONAL GUARD.

Dr. John V. Shoemaker, Surgeon-General of Pennsylvania, has published a circular for the government of the medical department of the national guard of the state, which consists of a surgeon-general, one surgeon with the rank of lieutenant-colonel, not more than twenty surgeons with the rank of major and not more than forty assistant-surgeons with the rank of first lieutenant. The assistant-surgeons who have served continuously for five years and are recommissioned within six months from the expiration of their former commission, will receive commissions as captains. The appointments of the medical department are made by the Commander-in-Chief, upon recommendation of the Surgeon-General and after the applicant has passed satisfactory examinations regarding his character, personal ability and physical fitness. The applicant must have been in active practice for four years before filing application. All the appointments to duty will be made by the Commander-in-Chief. The appointments of the medical department are as follows: On the staff of division commander, one surgeon with the rank of lieutenant-colonel; on the staff of regimental commander, one surgeon with the rank of major; to each regiment of infantry, one surgeon with the rank of major and two assistant-surgeons with rank of captain or first lieutenant; to each battalion of artillery and to each troop of cavalry, one assistant-surgeon with rank of first lieutenant. Medical officers will be appointed to commands within the territorial limits of which they reside.

HOSPITAL CORPS OF PENNSYLVANIA.

The hospital corps for each regiment of infantry consists of a hospital steward and one man from each company detailed for that purpose. The men detailed should be intelligent, should have had experience in caring for the sick and wounded. and preference should be given to men who have had military training. Each private of the hospital corps is furnished with a pouch containing a small flask of aromatic spirits of ammonia, six first-aid packages, a penknife, wire gauze, rubber bandage, gauze bandages, hemostatic forceps, pins and scissors. Acting hospital stewards are chosen from the privates of the hospital corps by their medical officers. Hospital stewards are selected from acting hospital stewards who have served not less than three months, are appointed by their medical officer and approved by a board of not less than three medical officers. Members of the hospital corps should receive instruction from a medical officer for at least eight hours in every month. The instruction will consist of lectures and demonstrations of methods of rendering first-aid to the sick and wounded, of drills in ambulance service and the duties of litter-bearers. The practical demonstrations should include the methods of arresting hemorrhage, applying first-aid dressing, extemporizing dressings for fractures, revival of those apparently drowned, the location of principal blood-vessels, treatment of faintness, heat exhaustion, sunstroke, etc. They should be taught how to take and record temperatures, make and apply poultices and plasters, and prepare sterilized dressings. They should also receive instruction in the art of preparing food for the sick.

Philadelphia.

Dr. W. W. Keen sailed for Europe, July 11.

Dr. S. MacCuen Smith will spend two months in Europe.

Dr. Arthur V. Meigs will spend the summer at Northeast Harbor.

Dr. Orville Horwitz expects to go to Bar Harbor at an early date.

Dr. George M. Gould, editor of the *Philadelphia Medical Journal*, started for Europe, July 18.

The Children's Country Week Association has sent about five hundred children to different portions of the country during the past few days.

Through the bequest of Elizabeth R. Blight, the sum of $10,000 has been left the Episcopal Hospital. A provisional bequest was also made to the St. Vincent's Home and Maternity Hospital.

Dr. F. Savary Pearce, instructor of physical diagnosis in the University of Pennsylvania, has been elected clinical professor of nervous diseases at the Medico-Chirurgical College, to succeed Dr. Charles W. Burr, resigned.

The experimental filtration plant built by the city at an expense of $10,000 is now almost ready to undergo proper tests. The water will be tested both bacteriologically and chemically several times a day.

OLEOMARGARIN LAW.

Many dealers who sell oleomargarin without license did not take the government at its word when the announcement was made that a crusade would be started to prevent this fraud. In one day, 10 men were arrested charged with this offense, later 5 more were added, and on July 14, 8 others. Several are serving terms in the penitentiary for their acts.

MORTALITY STATISTICS.

The number of deaths occurring during the past week was 633, an increase of 89 over last week, and an increase of 151 over the corresponding period of last year. The principal causes were: Apoplexy, 21; nephritis, 23; cancer, 21; cholera infantum, 96; tuberculosis, 65; pneumonia, 26; marasmus, 38; sunstroke, 33; diphtheria, 17; scarlet fever, 3; typhoid fever, 11.

BABY FARM.

Another so-called "baby farm" has been discovered in this city. It is said that some time ago there were several children placed at this house, but some of these have mysteriously disappeared. A short time since, dead infants were found on a vacant lot and the circumstances were such as to place the "baby farm" under suspicion. It is now believed that there may be more than one of these institutions in this city and a thorough search is being made.

FORTUNE TELLING.

Another crusade of a beneficial character to any community has been undertaken here. This is a warfare against what is known as "fortune telling." The mental impressions made on the minds of ignorant people by these impostors would doubtless startle one if the real facts were known. In this city, there is a law against the practice, and District Attorney Rothermel is pushing the charges against some of the guilty ones. Some time ago "Madame Dreyton" was sentenced to one year's imprisonment and also to pay a fine of $100 for this offense and it seems likely others will follow her. In one instance it is said a swindler of this character obtained $130 from a single victim.

ILLINOIS.

Dr. George N. Kreider, Springfield, assistant surgeon-general to the Second Brigade, I. N. G., has resigned. Dr. Charles B. Fry, Mattoon, has been appointed his successor.

The medical staff of the Moline hospital was organized July 10. The following officers were elected: president, J. W. Morgan; vice-president, E. A. Edlen; secretary, C. E. Whiteside.

Dr. E. W. Weis, chairman of the committee on publication of the *Illinois Medical Journal*, has gone to Europe, and Dr. Geo. N. Kreider will assume the editorial management of the *Journal* during his absence.

ILLINOIS PHARMACEUTICAL ASSOCIATION.

This Association met at the Chicago Beach Hotel, July 17, for its twenty-first annual session. The first day's proceedings were enlivened by Prof. C. H. Hallberg's attack on the present state pharmaceutical laws, which elicited a heated discussion. Professor Hallberg's contention is that the members of the state board of pharmacy should be named by the Association and not by the Governor.

DIPHTHERIA AND FAITH CURE.

A community in Whiteside County, which has started up a sort of Dowieite or similar faith-cure establishment seems likely to get into trouble with local authorities. The head of the concern, one Abram Zook, has lately claimed supernatural powers of healing and has started up a sort of orphanage. Diphtheria having broken out amongst the inmates, he refused any medical aid and there have been several deaths and nothing done until doctors were ordered there by the authorities. Three children had died up to last week and several more were in imminent danger at last accounts, according to newspaper reports.

Chicago.

Dr. Truman W. Brophy sailed for Europe on the *St. Paul* July 18.

Dr. George B. Dyche has returned from Europe, where he has been for the past year.

Dr. Harold K. Gibson, who has been studying in Europe for the past two years, has returned.

The will of the late T. B. Blackstone devises $25,000 to the Passavant Memorial Hospital and $25,000 to St. Luke's Hospital.

Dr. Nicholas Senn, who is now in Denver, is reported to have telegraphed the War Department, offering his services for the Chinese campaign.

The Home for Crippled Children has arranged for a new school building and hospital. The latter structure, which will cost $10,000, is the gift of Mrs. R. H. McElwee. It will be devoted to the surgical and medical care of destitute crippled children.

Dr. Adolph Gehrman, the city bacteriologist, has made a careful examination of the corned beef that was supposed to be responsible for the poisoning of so many last week, and has found ptomains in one specimen. An inspector has been sent to the different meat shops in that vicinity and a thorough investigation will be made.

TETANUS.

The tetanus statistics dependent on the national holiday are rather startling. Since July 4, twenty-five deaths from tetanus have been registered in Chicago. The majority of the cases were due to the "deadly toy pistol," but the gas-pipe cannon," blank cartridge and gunpowder each contributed its proportion. The deaths from tetanus during the same period in 1899 did not exceed fourteen.

HEALTH DEPARTMENT.

The bulletin for the week ended July 14 shows a death-rate of only 12.6 per 1000, which is the lowest rate for any week in July since the weekly record has been made. The corresponding week of 1899 had a mortality of 17.6 per 1000. The principal reduction is among infants and children under five years of age: In 1899, 281 died; in 1900, 149; a reduction of 47 per cent. The deaths from "impure water diseases" were 132 in 1899 and only 80 in 1900, a reduction of 56 per cent. This the Health Commissioner considers due to the generally good sanitary quality of the water. The intensely hot and humid weather of the past week was directly responsible for 17 deaths from sunstroke. The total deaths from all causes for the week was 423—242 males and 181 females—which compares favorably with the corresponding week of 1899, when 559 died. The principal causes of death were: Acute intestinal diseases, 77; Bright's disease, 23; consumption, 46; cancer, 15; heart diseases, 30; nervous diseases, 39; pneumonia, 22; suicide, 7; violence, 27. Seventy-nine cases of contagious disease were reported, namely: Scarlet fever, 33; diphtheria, 40; measles, 2, and smallpox, 2. The department laboratory made 48 bacteriological examinations of ice, meat, water and milk, and 25 for suspected disease; 478 samples of milk and cream were analyzed, 1.90 per cent. of which were found to be below grade.

IOWA.

Sioux City has arranged for a quarantine hospital, and work will be commenced on it in a few weeks.

The *Iowa Medical Journal*, formerly published in Fort Dodge, by Dr. J. W. Kime, will hereafter be published in Des Moines, and Dr. E. E. Dorr will be editor.

The Burlington hospital has received a gift of $5,000 from Mr. E. Hageman of that city. The money is to draw interest during his life, and at his death go unconditionally to the hospital.

MICHIGAN.

Work has been commenced on a forty-r
Detroit, that will cost $15,000.

A memorial tablet was dedicated at Mackinac Island, July 10, to Dr. William Beaumont. The inscription on the stone reads: "Near this spot, Dr. William Beaumont, U. S. A., made those experiments upon Alexis St. Martin, which brought fame to himself and honor to American medicine. Erected by the Medical Society of the Upper Peninsula of Michigan, July 10, 1900."

MORTALITY STATISTICS.

There were 2993 deaths recorded in the state during June. This is a decrease of 515 deaths from the previous month and represents a death-rate of 11.7 per 1000 population, as compared with 13.8 for May. There were 390 deaths of infants under one year of age, 158 deaths of children, aged 1 to 4 years, and 628 of persons aged 65 and over. The important causes of death were as follows: Pulmonary consumption, 149; other forms of tuberculosis, 44; typhoid fever, 31; diphtheria and croup, 25; scarlet fever, 15; measles, 25; whooping cough, 21; pneumonia, 152; diarrheal diseases of children, 82; cerebrospinal meningitis, 31; influenza, 18; puerperal septicemia, 15; cancer, 106; accidents and violence, 174; 1 death from smallpox in Springwells township. As compared with the preceding month there is a decrease in the number of deaths returned from pulmonary consumption, measles, whooping-cough, pneumonia and influenza, and a slight increase in the number of deaths returned from accidents and violence, largely due to the increased number of deaths from drowning. The death-rate of June, 1899, was slightly lower than that for the present year, being 11.5 per 1000.

CONNECTICUT.

Dr. Edward G. Fox, Wethersfield, has been appointed prison physician, to succeed Dr. Walter N. Thayer, Jr., resigned.

The Middlesex County Hospital Association has purchased a site for the building of a hospital, at Middleton, for which $12,000 has already been pledged.

Hartford.

At the meeting of the Board of Health, held July 6, Dr. Chas. S. Stern was elected medical inspector, and Dr. Chas. P. Botsford, assistant.

Dr. Frederick T. Simpson has been appointed consulting physician in insanity at the state prison, to succeed Dr. Melancthon Storrs, deceased.

MARYLAND.

SCURVY AT THE HOUSE OF CORRECTION.

Dr. C. P. Carrico, physician of the Maryland House of Correction, at Jessups, reports an outbreak of scurvy among the inmates, due to lack of proper vegetable diet. Of the 375 patients, 50 are affected. The affection is characterized by spongy gums and great muscular weakness; in many the teeth have fallen out, and others have contraction of muscles and swollen joints and limbs. The trouble seems to be too much economy. The chief food has been meat, and soup made of only beans and water. This condition of affairs, so discreditable to the public authorities, would not probably have been made known had not the institution lately gone into the hands of a new board, which is now investigating affairs.

Baltimore.

Dr. Thomas S. Cullen sailed July 14 for Paris.

Dr. J. W. Lord, secretary of the Medical and Chirurgical Faculty of Maryland, while descending a hill last week, fell from his bicycle and sustained a fracture of a clavicle.

Dr. Howard A. Kelly entertained the Deer Creek Farmers' Club, of Hartford County, at his country seat, "Liriodendron," near Belair, July 7.

DELAWARE.

The Delaware Hospital fund has reached $19,000, and the buildings will soon be commenced at *Wilmington.*

An investigation is being made in regard to an institution chartered some time ago under the name of the "University of Delaware." It is charged that this institution has been granting degrees in foreign countries. The institution, according to the charter, has a right to teach philosophy and dental surgery; and it is further provided that graduates in medicine, dental surgery or philosophy may become members of the institution. The "university" has no office in the State of Delaware. The corporators named are Dr. Charles Forster, a dentist, and Christian Plosser, a saloon-keeper of Wilmington.

CALIFORNIA.

Dr. F. C. E. Mattison, Pasadena, has gone to Paris as a delegate to the International Medical College.

At the commencement exercises of the College of Physicians and Surgeons, held July 5 in San Francisco, degrees were conferred on thirty-three by Dr. Winslow Anderson, president of the college.

WISCONSIN.

At the meeting of the State Board of Medical Examiners of Wisconsin, held in Madison, July 11, J. R. Current, Two Rivers, was elected president and H. M. Ludwig, Richland Center, secretary. One hundred and twenty-five licenses to practice medicine in the state were granted.

KANSAS.

Dr. F. M. Thomas has resigned as surgeon of the federal prison at Leavenworth, to take effect Aug. 1.

WASHINGTON.

The election of officers of the State Board of Medical Examiners was held July 5 and resulted as follows: President, P. B. Swearenger, Tacoma; vice-president, C. E. Grove. Spokane; secretary, W. G. Tucher, Port Townsend; treasurer, J. H. Dumon, Centralia. The next examination will be held in Seattle the first Tuesday of January.

MISSOURI.

Dr. Clarence Martin, of St. Louis, has been appointed an assistant-surgeon in the United States army and assigned to duty in the Philippines.

Dr. J. Harvey Moore, of St. Louis, has been appointed a member of the Board of Managers of the State School for the Blind, and will take charge of all the general work of the school, as well as pass on all applications for admission.

LOUISIANA.

The newspapers had a sensational report a few days ago to the effect that a new and terrible plague had broken out in Louisiana. However, Dr. Edmund Souchon, President of the Louisiana State Board of Health, reports that the disease is smallpox. An expert was sent to Caldwell parish, where fourteen cases were found, two deaths having already taken place. All proper measures are being taken to prevent the spread of the disease.

CANADA.

Dr. J. J. Mackenzie, bacteriologist to the Board of Health of Ontario, has been appointed professor of pathology in the University of Toronto; and Dr. J. A. Amyot, associate professor of pathology in the same institution, will become provincial bacteriologist.

ADULTERATION IN DRUGS.

An unusual kind of adulteration in drugs has recently come to the notice of the chief analyst of the Inland Revenue Department at Ottawa. It consists in the substitution of sodium nitrate for saltpeter, and seems to be very prevalent among grocers and general dealers, and even in drug shops. Particular attention will be paid by the department to the stoppage thereof in the drug trade. Samples of saltpeter are now being collected, and no doubt prosecution for contravention of the adhulteration act will follow in those cases in which the sodium salt is sold under this name.

ONTARIO ASYLUM DOCTORS TRANSFERRED.

Dr. R. H. Robinson, assistant superintendent at the Toronto Asylum for the Insane has been granted three months' leave of absence on account of ill-health, and Dr. J. F. Ross, assistant physician at the Brockville Asylum has been transferred to the Toronto institution in the same capacity. Dr. Herriman, who has been assisting at the Toronto Asylum, returns to Hamilton. Dr. D. D. Smith, assistant physician at Hamilton, has been transferred to Brockville, where he will be assisted by Dr. Wilson, assistant physician at the Mimico Asylum, who has been transferred to that institution; and Dr. McNaughton, second assistant physician at Brockville, assumes the duties formerly taken by Dr. Wilson at Mimico.

TINEA FAVOSA IN THE MARITIME PROVINCES.

Dr. George C. Melvin, St. John, N. B., has recently been looking into this disease with the idea of preventing its introduction to any extent into the provinces down by the sea. The recent action of the United States Government in excluding immigrants from landing at any of their ports of entry, and the ever-increasing importance of St. John as a port of entry, has prompted Dr. Melvin to issue a note of warning to local immigration officers. Although the immigration authorities of Canada have not yet taken any steps toward prohibiting the landing of these afflicted immigrants, it is altogether likely, now that their attention has been drawn to the danger of the introduction of this disease into our midst, that they will take the proper steps and precautions to prevent it. Dr. Melvin has recently been in New York, making a special study of the disease, as no large experience could be gained from private practice in St. John. He mentions a case in the service of Dr. T. G. Roddick at the Montreal General Hospital, where nearly the whole cutaneous surface was involved.

Montreal.

THE FOLLOWING have been appointed resident physicians at the Montreal General Hospital: Drs. E. R. Secord, C. K. P. Henry, W. G. Turner, J. W. T. Patton, W. H. P. Hill, L. M. Murray, W. E. Rowley, A. R. Hall and H. R. D. Gray.

TROPICAL AND SUB-TROPICAL DISEASES IN CANADA.

In *The British Medical Journal* of June 23, Professor Adami, of McGill University, addressed a letter to the secretary of state for the colonies, the Right Hon. Joseph Chamberlain, on this subject. This was in response to circular letters addressed to the Dominion Government which were by them forwarded to the medical faculty of the university. In his letter, Dr. Adami deals with malaria, dysentery, cholera nostras, typhoid fever, leprosy, mycetoma pedis, and some diseases of cattle, beri-beri, blastomycetic dermatitis and rabies. On three of these notes have already appeared in this correspondence to THE JOURNAL, namely, on malaria, rabies and leprosy. As regards dysentery, Professor Adami knows of only one case in which this disease occurred in a native who had not been outside the limits of the Dominion. He believes that in the southern part of the province of Ontario, investigations will show this disease to exist. Cholera nostras is much more common and more fatal in the large towns in Canada than it is in the British Isles; this is explainable by the changes of temperature in the summer months. There have been a few cases of beri-beri in one of the asylums outside of Montreal, clinically unrecognizable from this disease. Dr. F. Shepherd, Montreal, he states, has within the last few weeks studied and described two cases of blastomycetic dermatitis, in "habitants" of that district. As to mycetoma pedis or madura foot, Professor Adami says that Dr. Kirkpatrick of Montreal and himself were the first to report a certain case of this in America. This case occurred in a young French Canadian of Montreal, who had never traveled.

DIPLOMAS IN PUBLIC HEALTH AT M'GILL UNIVERSITY.

At the annual convocation of McGill Medical Faculty diplomas of Public Health were granted to four who took this special course: Drs. W. W. Ford, J. E. Laberge, H. S. Shaw and J. E. Williams. This is the first occasion on which these diplomas have been granted at McGill, which, so far as known, *is the first medical school on this continent* to carry out a diploma course of this nature. These graduates have taken special courses in sanitation and laboratory work on hygiene and have passed a special examination. Considering the paramount importance of the sanitary physician at the present day, McGill has no doubt inaugurated a move in the right direction in higher medical education; and in order that work of this character and scope shall prove eminently and fully successful, the importance of boards of health insisting in the public interest, that applicants for official positions should possess these qualifications, will assuredly be fully appreciated. This new diploma of McGill has been fashioned after similar qualifications given by some of the institutions of Great Britain. The outside sanitary work performed by the four graduates has been under the supervision of the medical health officer of Montreal, while the faculty work has been under the supervision of Dr. Wyatt Johnson.

LONDON.

THE ARMY MEDICAL SCANDALS.

The one department of the army which we have been assured on the highest authority is above criticism has now, in its turn, to defend itself against a very severe attack. Sir William MacCormac and Mr. Frederick Treves, on their return from South Africa, where they acted as consulting surgeons to the army, have only recently declared that never before in the wars of the world were such ample arrangements made for the care of the sick and wounded. The long, able, and exceedingly graphic and circumstantial description of scenes actually witnessed, published in the *Times* by Mr. Burdett-Coutts, M. P., gives a very different picture, and has created a profound sensation. It appears that there are 20,000 sick and wounded soldiers in South Africa, of whom more than half are ill from typhoid fever. In a field hospital which had accommodation for 50 patients, Mr. Burdett-Coutts says that he found 250. Men lay with their faces covered with flies in black clusters, too weak to brush them off, and with no one to do it for them. There were not enough orderlies at night to prevent delirious patients from wandering about the camp half naked in the bitter cold. Then the camp had to be evacuated, and patients suffering from typhoid hemorrhage were jolted across the veldt on rough ox-wagons. Near Bloemfontein hundreds of men in the worst stages of typhoid fever lay on the ground, some of them in three inches of mud, with only a blanket and a thin waterproof sheet. They had no milk, hardly any medicines, no beds, stretchers, mattresses, nor pillows, and not a single nurse, but only a few soldiers to act as orderlies. This was not at the time of a forced march; the neighboring town of Bloemfontein had been occupied six weeks. Along the railway countless trainloads of stores of all kinds passed for every one except for the sick. At this time many large buildings in Bloemfontein, which might have been used as hospitals, were occupied by officials.

The reply of the government in the House of Commons to these serious charges is that every possible arrangement has been made for the care of the sick, and that money has been lavishly spent. There are now 900 medical men serving with the troops in South Africa, and 18,840 beds have been provided, which are in excess of the number required. The case mortality from typhoid fever has been 21 per cent., which is less than that of many other campaigns; in the Nile campaign of 1898 it was 28 per cent., and in the Dongola campaign of 1896, 50 per cent. At the request of the government, Lord Roberts points out that the difficulties of transport were very great. He had to obtain supplies from a distance of 900 miles. He suggests that the government should appoint a committee to come to Africa and investigate the working of the medical service. No attempt has yet been made to answer Mr. Burdett-Coutts' *charges, and therefore the matter remains in a very* unsatisfactory state.

"FINSEN'S LIGHT TREATMENT" AT THE LONDON HOSPITAL.

A department for the treatment of lupus and other skin diseases, by the methods of Prof. Finsen, of Copenhagen, has been organized at the London Hospital. The apparatus in use is exactly similar to that employed by the Danish professor. Sun or electric light is passed through hollow lenses containing solutions which absorb the caloric rays: the ultra-violet or chemical rays are focussed on the [illegible] which [illegible] rendered anemic by pressure. Dr. [illegible] that these rays have considera[illegible] tients are photographed before, during and after treatment. A diseased area is selected by pressing on the reddened skin with a glass spatula, which renders the comparatively healthy tissues anemic and reveals any yellow lupoid nodules present. The skin is cleansed with oil of sesame, the diseased area marked with an aniline pencil and a piece of moistened lint with a hole corresponding to this area, applied. A spot of light about 3-5 of an inch in diameter is allowed to fall on the skin. After an hour's treatment a dressing of zinc carbonate and lanolin is applied. There is then no redness, swelling or pain, but from six to twelve hours later redness and swelling occur. After twenty-four hours bullæ often form, and some serous weeping, but rarely pustulation, occurs. If the area of disease is large, the periphery is first attacked with a circle of rings overlapping the healthy skin, and these are afterward carried concentrically inward. The tubercle bacilli are destroyed but the healthy skin is unaffected. This daily treatment may have to be continued for months. The results can not yet be stated.

NOMENCLATURE OF TRANSVERSE PRESENTATIONS AND VERSION.

At the Edinburgh Obstetrical Society, Dr. Berry Hart read a paper on "The Nomenclature of Transverse Presentations and of Version: Choice of the Leg Seized." He said that the best nomenclature in transverse presentations was that which divided them into dorso-anterior and dorso-posterior, and each of these into left acromio-iliac and right acromio-iliac, according as the acromion was directed to the left or the right in the mother. The positions were named after the acromions because this was often the presenting part. The nomenclature of version is very confusing. The terms used are descriptive either of the method or the aim. "Bipolar" and "External" are applied to the former; "Podalic" and "Cephalic" to the latter. There are three great varieties of version: 1, combined external version—cephalic—now seldom used, practically performed by external manipulation, its aim being to get the head to present; 2, Simpson's combined version (podalic) carried out by means of one hand over the abdomen and the other passed deeply into the uterus, the aim being to get the lower limb to present; 3, Braxton Hicks' bipolar version (podalic), performed with one hand external and the other internal, but not deep, that is, not passed beyond the presenting part. In the choice of the leg both the seizure of the further knee and the nearer foot have been advocated. In a simple case either leg might be seized. In difficult cases, with the liquor amnii drained off, it is important to seize the knee which gives the safer operation. Dr. Hart's directions are: "Seize the knee or leg which maintains the dorso-anterior position or converts the dorso-posterior into dorso-anterior—that is, take the further limb in dorso-posterior cases, the nearer in dorso-anterior. When, however, in dorso-anterior cases, the breech is in the fundus, traction on the nearer leg may convert the case into a dorso-posterior one, and when the breech is near the os, in dorso-posterior position, traction on the farther leg may not alter the posterior position of the back after version, owing, again, to want of the necessary obliquity in the pull."

LIVERPOOL SCHOOL OF TROPICAL MEDICINE.

The enterprise of the Liverpool School of Tropical Medicine, which has been founded only a year, is most extraordinary and quite puts to shame older institutions. It had not been founded two months before it sent an expedition under Major Ross to West Africa to investigate malarial fever. Soon a second expedition was sent, and now a third has started for America, with the principal object of investigating yellow fever. The expedition will visit, by invitation, the Army Medical Department at Washington and the Johns-Hopkins University at Baltimore, and confer with the bacteriological experts there. It will then sail to Para, Brazil. Advantage will be taken of the opportunity to test still further the work of the school in malarial fever carried on by Major Ross, and to study dysentery and other tropical diseases from which British sailors suffer so much. That expeditions of this kind have never been undertaken by the government but are left to the private enterprise of a provincial medical school is a startling example of the neglect of science by the authorities, which is so proverbial in Great Britain. At one of the meetings held in support of the expedition, Major Ross said that the want of intelligence and enterprise, the sluggishness of thought and action as regards tropical sanitation are worthy rather of the Chinese Empire than of any civilized nation. The German government voted £6000 two years ago for a commission to study tropical diseases and yet the greatest tropical power in the world has never voted a penny for this purpose.

Correspondence.

Colored Tents for Hospital Corps.

Mobile, Ala., June 28, 1900.

To the Editor:—A medical officer of the British Army, operating in South Africa, has recently pointed out the difficulty of distinguishing the red cross as now displayed, at distances even of three or four hundred yard during calm weather, when the Red Cross flag hangs limp from the flagstaff.

Recent reports of opposing forces firing on the Red Cross have been published, and no doubt, in some instances, these attacks might be accounted for by this fact.

Would it not appear advisable to equip the hospital corps with tents of different color from those of the troops in the field, and to uniform the members of the corps in a color so distinctive that they could be recognized at a distance. If the hospital tent were of solid green color, and the hospital corps wore a red jacket, it would be possible to readily distinguish this branch of the service from combatants, at much greater distances than is possible with the present equipment.

T. B. Perry, M.D.

Department of Ethnology and Archeology, Pan-American Exposition.

Buffalo, N. Y., July 3, 1900.

To the Editor:—The Pan-American Exposition has seen fit to entrust the care of the Department of Ethnology and Archeology to a practicing physician. I should be very glad if you would allow me to reach your readers with the following request for assistance: Many members of the medical profession are interested in the study of American Ethnology and Archeology, and not a few have valuable collections of Indian relics and skeletons from Indian graves. Those not directly interested in this study are so circumstanced as to be aware of the hobbies of their neighbors and could doubtless furnish the address of collectors. I should be greatly obliged for information and for the loan of collections for the use of this department of the Exposition. Exhibits which represent study in some special line of American Ethnology and Archeology will be particularly suitable. A. L. Benedict, Superintendent.

A Model Society.

Hartford, Conn., July 18, 1900.

To the Editor:—Medical societies and their progress are always subjects of interest. The Thurber Medical Society is a model and in some ways an object-lesson of great value. The town of Milford, in Worcester County, Mass., had a very noted physician many years ago. He was not only a physician of eminence, but one who made friends, and was literary in his tastes. In 1853 a little group of physicians formed a society for medical improvement and the cultivation of good fellowship, and named it after him. They soon began to collect a library, and received donations from outside, and became incorporated by an act of the legislature. This society has been in existence up to the present time. One hundred and eleven persons are numbered among its members during these years. The average attendance at each meeting is from fifteen to thirty, and this in a country village where many of the members must drive from five to ten and fifteen miles to reach the meeting. During all these years meetings have been held every month for at least eight or nine months during the year, and at each meeting from one to four papers have been read and discussed. Many of these papers have been published; others have been filed away in the library. During the last few years the interest has increased and also the number of papers offered, until now it is looked forward to as an afternoon holiday and post-graduate school for all the physicians in that neighborhood. Often patients are brought into the room and examined and commented on. Every year a dinner is added to the attractiveness of the occasion. These members coming from their active work meet at 2 p. m., and leave at 5 or 6, rarely spending longer time. The business of the society is not touched with politics nor personal considerations for its honors. The secretary has been continued for many years, and the president serves his year without ambition to be continued. Each one seemingly has the central object before him to learn something new and be sustained by the good opinion of his fellows. Two generations of physicians have come and gone as members of the Thurber Medical Society. The library and records have steadily grown with the value of the meetings. It is doubtful if there is any other country local society in the United States which has gone through forty-seven years of persistent activity and usefulness equal to this. All the members belong to the Massachusetts Medical Society, but have no affiliation with other societies and send no official representatives. I think this record is unsurpassed and should be given a wide publicity.

T. D. Crothers, M.D.

Varicose Veins.

Wilkesbarre, Pa., July 11, 1900.

To the Editor:—In the Aug. 7, 1897, issue of The Journal was a short description of an unusual case of varicose veins, together with a photographic cut of the patient. The case was one of compensating dilatation of the superficial epigastric and superficial circumflex iliac veins on both sides of the abdomen, following an attack of phlebitis involving both the right and left femoral veins, which permanently obliterated the lumen of both vessels.

The patient died a few days ago from hemorrhage of the stomach. During the past two years he had suffered from dropsy in both legs, the scrotum and abdomen, ulcers on both legs and many other symptoms due to obstruction to the return circulation from the lower limbs.

Thinking there might be others who would be interested in knowing how the case has terminated, I submit the above.

B. J. Wethersby, M.D.

Cocain Habit Among the Negroes.

Memphis, Tenn., June 27, 1900.

To the Editor:—I have just read your editorial in The Journal concerning the cocain habit in the negro. It is safe to say that two-thirds of the negroes who are addicted to the use of cocain use it by the "sniffing" method. We have here in Memphis "dives" called drug stores, whose sole trade is to sell cocain to the negroes at night. The sign, placed in a conspicuous place in one of these resorts, "Open all night," is an index to what they dispense—cocain. I see a great many of these "cocain sniffers" in my outdoor clinic and my observation is that the habit leads up to acute mania. I have been reliably informed by a night clerk in one of these drug stores that he has dispensed as high as one hundred and fifty packages of cocain during the night. The cocain habit is one of the greatest evils to which the negro is addicted. Frequently in the police court when arraigned for cutting, shooting, or running "amuck," his plea is "*C-o-a-c had me.*" The "cocain sniffer" is found among the lowest and most ignorant class, both white and black. The evil is growing all the time in Memphis. The following ordinance has recently been enacted:

Hereafter no person, firm or corporation shall, within the limits of the city of Memphis, sell or give cocain, or any preparation, compound or mixture of cocain, or its salts, to any person in any quantity less than one pound, unless the person offering to purchase shall produce a certificate from a practicing physician stating that such person needs cocain for his or her physical welfare, and a separate certificate shall be produced for each purchase. Each certificate shall bear the date on which it is issued, and no sale shall be made on such a certificate except on the date on which said certificate is issued, and the certificate shall be delivered to the person making the sale, and filed by him, and such certificates shall be open to the inspection of the Police Department of the city at any time.

Any person violating this ordinance shall be fined not less than $2 nor more than $50 for each offense, and each sale shall constitute a separate offense.

Frank A. Jones, M.D.

Scandinavian Leprosy.

New York City, July 2, 1900.

To the Editor:—Referring to your encouraging remarks on "Leprosy in Wisconsin," which appeared in The Journal of June 30, will you permit me to say that no one disputes the proposition that if time enough be given, leprosy will eradicate itself by death of the patient. Hansen said in the Berlin Leper Conference: "Wait fifteen years and your German lepers of Memel will be dead." But why did it require so much longer to eradicate leprosy from his own country? Because his isolation there was two-thirds in families and but one-third in hospitals. Had he instituted perfect isolation, perhaps his fifteen years' limit would have been sufficient.

You state that Dr. Wingate said that the germ of the disease appears in his climate to find little suitable soil in the native-born population, at least up to date, etc. Let me inform you —perhaps you know it already—that immigration of lepers into a new country of those predisposed through inheritance—and as great a man as Besnier believes in inheritance—to leprosy will retard the outbreak of the disease, perhaps one or two generations, in the family line. Hereditary predisposition and some other still unknown cause peculiar to sea climates are the two principal factors, it is believed, in the development of leprosy. I believe that it is a certain insect life of the climate, together with another factor, perhaps a double intermediary-host one, which produces the eruption of the disease.

It is a curious fact that up to the twelfth and thirteenth centuries leprosy advanced northward through Europe; that is from a hot to a cold climate, and there was no difference between the disease in the cold climate and in the hot—in fact, it has disappeared from the hot countries of Europe more completely than from the cold. If Wisconsin, a cold climate, is inimical to the germ, why has this occurred in Europe?

Now, for some interesting facts: Some years ago I sent back to Japan a native in whom there had developed in New York what I had diagnosed as vitiligo. Both his hands had turned white, commencing at the tips of his fingers. To-day that man is an anesthetic leper. In Nagano Ken the silk district of Japan, a young Japanese woman was about to be married. It was said that her brother was a leper, and, in consequence, the bridegroom's relatives insisted that he should give her up. He refused and they ostracized him and his wife. The popular opinion in Japan is that leucoderma or anything resembling it is degenerate leprosy, or an abortive type of the disease occurring in certain families, and that true leprosy will reveal itself in some later generation.

In the Scandinavian population of the Northwest leucodermatous afflictions are plentiful, as I am told. May not this fact have something to do with the non-occurrence of real leprosy in the second generation of lepers' blood there, and may not a third or fourth generation reveal the true type of the disease?

At any rate, let us be on our guard until we are sure of it. Even without leprosy, immigration of families whose European relatives were lepers may breed lepers in the third or fourth generation, and even in so dry a climate as that of Wisconsin.

Albert S. Ashmead, M.D.

Typhoid Fever in Camps During the War with Spain.

War Department:
Chickamauga and Chattanooga National
Park Commission.
Washington, July 12, 1900.

To the Editor:—Allow [illegible] you [illegible] published the most i[illegible] article [illegible] yet appeared regarding [illegible] ps [illegible] war with Spain. Eve[illegible] military duties to perform, and every officer who served with troops should procure this article and give it careful study. I refer to the paper of Major Victor C. Vaughan, of the University of Michigan, late division surgeon, U. S. V., published in your issue of June 9.

The report of the board of surgeons of which Major Vaughan was a member, with Major Walter Reed, U. S. A., chairman, and Major E. O. Shakespeare, U. S. V., has been awaited with deep interest, not only by all medical officers of the service, but by all the general, line, and staff officers charged with the organization of troops in the various camps of the recent war. While this paper does not purport to be a synopsis of the forthcoming report, it doubtless presents many of its main points, and at the same time sharpens the general desire to see the official report. All who had occasion to observe the exhaustive work of Major Reed's board in the great camps are confident that its report will be not only of national but of international importance.

The chief object of this communication is to ask space for a brief corrective and explanatory statement concerning the following paragraph in Major Vaughan's paper:

> Official statements that certain commands escaped typhoid fever have been made. Gen. H. V. Boynton, chairman of the Chickamauga and Chattanooga National Military Commission, in his report to the Secretary of War, under date of Oct. 17, 1899, makes the following statement:
>
> "At the time the camp was abandoned, it is true that there was much sickness, and that a condition approximating panic prevailed with many officers and surgeons. There were large numbers of fever patients in the hospitals. Seven battalions of troops—four colored, under Col. E. L. Huggins, of the Eighth United States Volunteer Infantry, and three white, under Col. L. D. Tyson, of the Sixth United States Volunteer Infantry—were left at the camp. The strictest sanitary measures were at once adopted by these officers, and were also rigorously enforced, both as to the camp sinks, the cooking of food, and the eating of trash, and the drinking of slop. The result was that, notwithstanding they were encamped in the same sections of the Park (Chickamauga) where the departing troops had been, not a case of fever developed in either of these forces, nor did a death incident to camp disease occur."
>
> This positive statement from one so high in authority needs careful investigation.

This was a report made to the Secretary of War in regard to typhoid fever, and it had no reference to other forms of fever. Quite naturally, and in the absence of information on the subject, Major Vaughan in his comments has considered the above report to the Secretary as covering for the Sixth United States Volunteers the period from August 24—the date when the first case of typhoid fever was found in the regiment, to October 4—the date when the command left Camp Thomas for Porto Rico. As a matter of fact, the report related only to the period from September 16 to October 4—the camp having been broken up on September 15, and the rigid sanitary measures to which reference is made having been put in force in part on September 16, under my general command, and completed September 19, by promulgating in orders specific and most excellent suggestions received from the board of which Major Vaughan was a member, then in session in Knoxville.

The sickness, therefore, between August 24 and September 16, which was very considerable, upon which Major Vaughan comments, and which apparently shows serious error in my report, does not belong to the period to which the report relates.

The statement that no deaths incident to camp disease occurred from the time the rigid sanitary measures were adopted is shown by the official records of the two regiments involved to be strictly true for the time which the report to the Secretary covers; the case of typhoid fever which Major Vaughan cites as having developed October 25, in the Eighth Regiment having been rediagnosed as malaria, and the patient subsequently returned to duty.

The following official report of the Surgeon of the Eighth United States Volunteers, covering a period more than three months later than my own, as well as the entire time to which that refers, is sufficiently explicit as to the health conditions in that regiment:

Office of the Post Surgeon,
Camp George H. Thomas.
Chickamauga Park, Ga, Jan. 28, 1899.

Sir:—I am directed by the commanding officer, Col. E. L. Huggins, Eighth Vol. Inf., to reply to your inquiry with reference to the sick report of the troops stationed at this post, and in compliance with these directions, I have the honor to state that the average number of troops from Oct. 9, 1898 (date of arrival), until Jan. 20, 1899, was 1150; and since the latter date, 950. During the 111 days of the present encampment, there were treated in the post hospital a total of 118 separate cases, of which 31 were measles, 7 gunshot wounds, 40 were due to the imprudence of the patients, and the remainder were nearly all due to grip. Since the first day of the organization of the first company of this regiment—June 1, 1898—there has not occurred a single death from disease in this regiment, nor among the troops attached to the regiment for service, and the only death from any cause was the accidental drowning of a man in the Ohio river last July.

Not a single case of typhoid fever has developed among the men since their encampment at Chickamauga.

None of the diseases treated here can be traced to the water.

Very respectfully, Your obedient servant,
James H. Hepburn,
Major and Surgeon Eighth Vol. Inf., Post Surgeon.

In regard to the Sixth United States Volunteers, the records in the War Department show that there were no deaths from typhoid fever within the dates covered by my report except two where the fever had been contracted the week before the camp was broken up, and so properly belonged to that period, and one from an attack which originated within the period covered by the report to the Secretary, namely on September 25. This death occurred at Sternberg Hospital, October 6, two days after the regiment had left for Porto Rico, and no report of it was received previous to the date of my report to the Secretary of War. From the date of its development even this case can be properly referred for its incipiency either to the last days of the general encampment, or to the very first days of the period when the more rigid sanitary measures were undertaken, and before they could have operated to materially change conditions.

My statement to the Secretary that no cases of typhoid developed, was based, so far as it related to the Sixth regiment, upon verbal statements by two of the field officers. The official medical reports did not pass through my hands, as they were sent direct to the brigade headquarters at distant camps to which the regiments, left at Camp Thomas as a guard to the stores, belonged. This will account for the error of my statement in regard to fever cases in the Sixth regiment, which Major Vaughan clearly points out.

The total absence of the development of typhoid fever in the Eighth United States Volunteers, during their encampment at Chickamauga Park from October 8 till January 28, certainly shows the good results of the rigorous sanitary precautions adopted, which included, as the most important, the enforcement in orders, of the suggestions received from Major Reed's board.

As contributory to the subject which Major Vaughan so ably discusses, it may be of interest to state that the Park Commission began the restoration of the Park August 15, and from that time until the latter part of December a force of 150 laborers was engaged in filling sinks, over 3000 in number and very filthy, *in filling camp and tent ditches, and clearing up and* restoring hospital sites. They drank the water from the same sources which the troops had used. Careful observation was made of the sanitary condition of this force by the park authorities, with the result that no typhoid fever developed among the laborers during the entire period in which they were engaged in park restoration.

It may also be of interest to know that, in spite of the sensational reports which were current at the time declaring Camp Thomas to be a "pest hole," the deaths among the 75,000 soldiers who were encamped there, first and last, as shown by the muster-out rolls, where every death is accounted for, were a little less than .5 per cent.

The regulars who were encamped there, embracing seven regiments of infantry, six of cavalry, and ten batteries, lost but one man from disease, that being a case of pneumonia contracted through carelessness and not in the line of duty.

H. V. BOYNTON,
Chairman of Commission.

Rambling Notes of a Roving Doctor.

PARIS, FRANCE, June, 1900.

To the Editor:—The Vienna school of medicine probably represents the most perfect type of the conservative treatment of the sick, of any school in existence. Years ago, when Bamberger was chief of the first medical clinic here, although he taught all the fine points in symptomatology and pathology, and took his students to the dead-house nearly every day to illustrate on the cadaver the correctness of his diagnoses, he said but little about the treatment of the sick. Nothnagel, who now fills this chair, although he gives more medicine than his predecessor, is still very conservative in his therapeutics. He says, "When you are called to see a patient, examine it well, make the best diagnosis that you can, and when you have done this, never ask yourself first, what medicine you shall give, but always precede it by the question, 'shall I give anything at all?'" He says that when he began the practice of medicine he used nearly every remedy contained in the pharmacopeia, but as years passed by he dropped one after another as unreliable, until now he can count on the fingers of both hands the remedies that he employs.

TREATMENT OF CHILDBED FEVER IN VIENNA.

Few cases of this disease are found among the patients who come to either of the three sections of the Allgemeine Krankenhaus to be confined. Most of the cases one sees are those who are taken in labor outside and, on account of some complication in the case, are brought here for relief after they have been in labor for some hours.

If a woman, after labor, is taken with a chill followed by a rise of temperature, that does not fall again to nearly normal within from 12 to 24 hours, the patient is put under the influence of an anesthetic and a thorough examination of the whole genital tract is made. Abraded or unhealthy spots in the vagina are touched with a mixture of one part each of tincture of iodin and carbolic acid and two parts of alcohol.

If the womb be closed up so that it will not admit the index finger, it is dilated with a Hegar dilator and thoroughly examined. If there be any decidua or placenta found within the uterine cavity, it is removed with the finger. This done, the womb is either swabbed out with the above-mentioned mixture, or irrigated with a 1 to 2000 carbolic-acid solution. Sometimes a small piece of gauze is packed into the womb, and left for a few hours as a drain.

No curetting is done, and no treatment of an intrauterine character is afterward resorted to. Dr. Schmidt, the chief assistant of Professor Schauta, told me that they had given the antistreptococcus serum a thorough trial, and had found it not only worthless, but absolutely harmful and had abandoned its use entirely. The internal medication is of an entirely supporting character, consisting of alcoholic stimulants and a nutritious and easily digested diet.

Ice bags are kept constantly over the lower abdominal walls, and if the temperature be very high, they are made to include all the bowels and lower part of the chest. Speaking of the dilation of the womb reminds me that during a period of two months I saw in the dead-house three cases where death had been produced by a rupture of the lower segment of the uterus in doing this operation. Two of these cases were those in which the patients suffered from puerperal eclampsia, and the other was one in which a rapid dilatation was being done to remove a placenta after an abortion.

Steel dilators, such as we often use in the United States, are never used in Vienna. The Hegar is used in all ordinary cases, and when these do not dilate the os sufficiently, the Barnes bag is resorted to.

GYNECOLOGY IN BUDAPEST.

While in Vienna I made a side trip down the Danube to Budapest. If the weather is fine, the day's sail down this historic and picturesque stream is a most enjoyable one. Then again, the Hungarian capital is one of the most beautiful cities I have ever seen, and I wonder that so many tourists leave it out of their European itinerary.

While there I visited the two gynecologic clinics that are connected with the National Medical School. These institutions, like nearly all the public buildings I saw there, seemed to be constructed after an ideal model in which beauty and architectural taste were the only things taken into consideration, and where the question of cost seemed to be entirely ignored. The first clinic had suffered from a fire a few days before my arrival, and hence, I did not see it at its best. In the second, however, I found an institution in which the theory of antisepsis was carried out more perfectly than I ever before saw attempted.

The operating-room was simply one huge marble compartment. After every operation, sterilized water was turned in a perfect flood on this room, washing every part of its surface from ceiling to floor.

Dr. Katzmarzky, chief of the first clinic, was out of the city at the time and I did not see him, but his first assistant, who is a graduate of the Paris School of Medicine, showed me everything of interest in the place, and answered all my questions with a true Parisian politeness.

The plan of treatment they adopt here in cases of puerperal fever, is essentially the same as that pursued in Vienna, and their experience with the antistreptococcus serum has been equally unfortunate.

Dr. Tauffer, chief of the second gynecologic clinic, received me as if I had been a long-absent brother, and I never spent a more agreeable or profitable three hours than I did in his company. I saw him do some good abdominal work, the peculiarity of which was that he closed the peritoneum and next adjacent tissues with a row of buried silkworm-gut sutures, using silver wire to close the muscles and integument.

Dr. Tauffer takes a bath before operating, changes all his clothes, and requires all persons who witness his operations to array themselves in tightly fitting, sterilized gowns. After all these precautions I was surprised to have him bring a patient before us for an abdominal section in which nothing had been previously done to disinfect the field of operation. The parts were washed with brush and soap, then shaven, and after that washed alternately with alcohol and ether. All this process occupied less than ten minutes' time.

As far back as 1889, Dr. Mikulicz, of Basle, recognizing the fact that the skin through which the surgeon must cut and the cuticle of his own hands could not be made thoroughly aseptic, introduced the wearing of rubber gloves by the operator, a practice that is being adopted by an increasing number of surgeons. I had a long talk with the Doctor on the management of puerperal sepsis, a subject to which he has given a good deal of attention. He says that he always looks early after the inside of the womb, and if any source of infection can be found upon its surface, he removes it, but with as little violence as possible.

From whatever point your infection may originate, he believes that from 48 to 72 hours after the first symptoms have manifested themselves, the *materia morbi* has gained access to the lymph-channels and through them into the blood, so that after that period you must consider your case as one of general infection. He says that in his hands the antistreptococcus serum has never done any good, but often harm. He says that microscopic research has convinced him that the whole theory upon which the use of the antistreptococcus serum is based is a false one, for you never have a simple streptococcus poison, but always a mixed one in which it is impossible to say which element plays the most important rôle in your morbid process.

In Professor Winckel, of Munich, I found a true type of the German, as well as a warm friend of America. In fact, all foreign physicians of any note who visit the United States are astonished at the warm reception they receive, and are always warm friends of ours ever afterward. Professor Winckel lives in a building located within the same enclosure as that of his Frauen Klinik, and devotes his entire time to his duties as a teacher and a writer. He will do outside practice under special circumstances, such as, for instance, attending royalty in childbed, and a few others who will pay him a couple of thousand dollars for his services. I saw him do some abdominal work, in which he sits on a high stool between his patient's legs, a la Martin, of Berlin, and operates with most consummate composure and skill.

In closing the abdomen he uses only catgut, burying the first two rows of stitches that close the peritoneum and muscles. The worst feature of all the surgical work I see done on the Continent is the unskilful manner in which they administer an anesthetic. It would seem that if an assistant is too stupid to do anything else, they allow him to give the chloroform. I was standing at the head of the woman that Winckel was operating on. The woman had her head bent forward and soon began to breathe hard. The anesthizer caught her tongue with a great heavy pair of forceps and began to pull upon it.

The patient breathed worse and worse, and grew black in the face. I could stand it no longer, and, seizing the angles of her lower jaw pulled them well up, throwing her head back, and in a moment she breathed better. Winckel chided the young fellow and told him I had taught him something, but why he had never been taught that simple procedure before I could not understand.

Winckel's treatment of the septic processes that follow childbearing is pretty much in line with that I have before quoted. The antistreptococcus serum that he has tried has never done any good, but often harm. He attributes its bad effects to the impure quality of the article used. In teaching his class on the management of the after-birth at term, he dwelt on the tendency of many accoucheurs to be in too much of a hurry. He advised waiting at least two hours before trying to produce uterine contractions, unless some urgent symptoms arose in the case.

GYNECOLOGY IN STRASBURG.

I stopped for a few days, while on my way to Paris, at Strasburg, where I saw some good surgery, and had a couple of long interviews with Professor Freund, whose acquaintance I made many years ago in Berlin.

Professor Fruend, though growing old, does all his surgical work himself, with the aid of very few assistants. The Professor is exactly of my own age; we received our medical teachings mainly from the same source, pursued an expectant plan of treatment with our early cases of puerperal disease, then grew more meddlesome and lost more of our patients, and later drifted back to nearly where we first began.

I was highly pleased to find a man of such eminence as Professor Freund, whose experience had been like my own, and who had arrived at the same conclusions as myself. He says, "If I have a case of peurperal fever on my hands I clear out the womb and cleanse it once, and then let it alone. Remedies of all kinds, save those that sustain the patient vitally and enable her to continue to battle with the disease, are perfectly worthless. I tried the antistreptococcus serum, but found it to do more harm than good."

CLINIQUE BAUDELOCQUE.

At the service of Professor Pinard, at the Clinique Baudeloque, in Paris, I found the only place where they still continue to use the antistreptococcus serum as a remedy for childbed fever.

Professor Pinard tells me that his first experience with this remedy was an unfavorable one, the patients often developing abscesses at the point of injection, as well as other symptoms of an unfavorable character. Latterly, however, he has gotten his serum from the Pasteur Institute, and since using this has had no bad effects from the remedy, though he can not yet say that he gets any benefit from it.

Besides the use of the antistreptococcus serum, they use a constant irrigation of the womb with sterilized water for from two to four days, and have more faith in this than any other remedy. When I asked Professor Pinard how he treated childbed fever, he replied at once: "We have none to treat." In fact, the statistics at the Baudelocque for ten years show this disease to be extremely infrequent. During that time the largest mortality during any year was .42 per cent, and the lowest .15 per cent.

W. S. Caldwell, M.D.

Association News.

Is Your Address Correct?

A list of members of the American Medical Association will be published in an early number of The Journal. It is important that this list be correct, and we would, therefore, ask each member to examine the label on his wrapper and, if not correct, notify us immediately so that the name may be correctly printed in the list. Subscribers who are eligible for membership and desire to be enrolled are requested to make application at once so that their names also may appear in the published list.

Deaths and Obituaries.

John Ashhurst, Jr., M.D., L.L.D., Philadelphia, died July 7, at the age of 61 years, after suffering for nearly two years from the effects of a stroke of apoplexy. He was born in Philadelphia, in 1839; at the age of 14 years he entered the department of liberal arts in the University of Pennsylvania, from which he was graduated in 1857. Three years later he received his degree in medicine from the same institution. During the Civil War, he was resident physician of the Pennsylvania Hospital, and acting assistant-surgeon in the Chester Hospital and the Cuyler General Hospital at Germantown, where he served as executive officer until 1865. He had also been surgeon of the Episcopal Hospital and of the Children's Hospital and a member of the surgical staff of the University of Pennsylvania Hospital and had acted as consulting surgeon to the Hospital of the Good Shepherd, to the St. Christopher's Hospital for Children, and the Woman's Hospital. In 1877, he was elected professor of clinical surgery in the University of Pennsylvania, in 1888 was made Barton professor of surgery, and in 1890, president of the College of Physicians. He was president of the Philadelphia Pathological Society from 1870 till 1877 and had served as vice-president of the surgical section of the International Medical Congress, of the American Surgical Association and the Philadelphia Academy of Surgery. He was a member of the American Medical Association, the Academy of Natural Sciences, the Philadelphia Academy of Surgery and numerous other medical and scientific societies. Among his most important books are "Injuries to the Spine" and "Principles and Practice of Surgery." He also assisted in the compilation of a medical dictionary and was the editor of the "International Encyclopedia of Surgery." He was also a frequent contributor to different medical journals. Notwithstanding the exacting duties of his profession, he found time to take an active interest in the affairs of the Episcopal church and in many charitable and religious enterprises. Dr. Ashhurst was one of the best-read physicians of the present day. As a diagnostician he had few equals. His knowledge of medicine covered a wide range and his remarks always commanded the closest attention.

Henry F. Hereford, M.D., Kansas City, Mo., died July 5, aged 72 years. He was born in Tecumseh, Ala., but spent most of his youth in Missouri. In 1849 he was graduated from the St. Louis Medical College. After spending two years in Mexico, he located in Westport, Mo., where he remained until the Civil War began. At its close he located in Kansas City, where he practiced his profession until his retirement in 1886. He was one of the organizers of the University Medical College of Kansas City and was president of the faculty and professor of obstetrics until 1886, when he retired on account of poor health.

Gerald Freeman, M.D., surgeon of the Allan Line steamer *Carthagenia*, was lost overboard July 6, while entering Halifax harbor, on that vessel's return voyage from Liverpool. He was a graduate of the Royal College of Physicians of Ireland.

Chas. P. Judkins, M. D., Cincinnati, Ohio, died very suddenly of heart disease, July 2, aged 57 years. He was graduated from the Miami Medical College of Cincinnati in the class of 1867.

CHAS. D. WALL, M.D., died at his home in Columbus, Ga., June 28, aged 32 years. He was graduated in the class of 1894 from the Louisville (Ky.) Medical College, and had practiced in Columbus, where for two years he was city physician. He was also secretary of the Columbus Academy of Medicine.

FRANKLIN GAUNTT, M.D., Burlington, N. J., died July 8, from blood poisoning contracted while performing an operation. He was graduated from the medical department of the University of Pennsylvania in 1841. He was a member of the State Board of Health, and of the New Jersey and Burlington County medical societies.

FRANK T. LINCOLN, M.D., died at his home in Savannah, Ga., June 28. He was a graduate of Trinity College, Hartford, Conn., and of the University of Maryland Medical School. He was a yellow fever immune, and during the epidemic at Brunswick, was station by the government at Jesup.

J. T. HEAPS, Delta, Pa., died in Johns Hopkins Hospital, Baltimore, Md., July 1, after an operation for abscess. He was a graduate of the College of Physicians and Surgeons, Baltimore, in the class of 1878.

MAHLON C. DIX, M.D., Hinsdale, N. H., died June 27, aged 56 years. He was born in Vermont, and was educated at the Albany Academy in that state. In 1875 he received his degree in medicine from the University of Vermont, and the same year located in Hinsdale.

H. M. CRAWFORD, M.D., St. Charles, Ill., died June 28, aged 80 years. He was a graduate of the Royal College of Surgeons, Ireland, from which he secured his degree in 1848, and the same year came to America as a ship's surgeon. Soon afterward, he located in St. Charles, where he remained uninterruptedly.

SAMUEL H. BIRNEY, M.D., a graduate of Rush Medical College, 1861, died at his home in Urbana, Ill., July 5, from malignant disease, aged 66 years. He was twice made vice-president of the Illinois State Medical Society and was at one time president of the Champaign County Medical Society.

THOMAS P. EDWARDS, M.D., died at his home in Newark, N. J., July 4. He was graduated from the University Medical College, New York City, in 1885.

DEATHS ABROAD.

We note the deaths of:

J. ICARD, M.D., editor of the *Lyon Médical.*

MAXIMINO TEJIERO, M. D. rector of the University of Santiago, Chili.

PROF. DE BONIS, of Naples, author of numerous works on pathology.

WILLY KUEHNE, M.D., professor of physiology at the University of Heidelberg.

F. RUBINSTEIN, M.D., a younger member of the profession in Berlin, whose name is familiar as a frequent contributor to scientific literature.

DR. SILVA ARAUJO, Rio Janeiro, who was the first to use the term "filariosis." The National Academy of Medicine has ordered a bust of the deceased, and organized a movement to found "a cancer hospital to be called the Dr. Silva Araujo Hospital." It also voted to retain his name as perpetual president of the academy.

JULIUS ALTHAUS, M.D., who died in London, June 11, was born in Detmold, Germany, in 1833, and received his degree in medicine from the University of Berlin 1855. He settled in London shortly after and has been prominent among English physicians for many years, especially as a consultant in disorders of the nervous system. He is best known perhaps by his work on "Medical Electricity," but has published many other works and papers.

RAW MEAT IN EXPERIMENTAL TUBERCULOSIS.—Richet and Héricourt announced at the meeting of the Paris Société de Biologie, June 2, that they inoculated a number of dogs with tuberculosis more than six months ago. One-third were fed with ordinary food and all died in three to four weeks; another set, with cooked meat, with about the same results, while the third group was fed exclusively with raw meat, and all have survived to date and are in good health.

Miscellany.

Tomb of Avicenna.—A Russian confrère, passing from Teheran to Bagdad, visited the tomb of Avicenna, in ancient Ecbatana, the capital of Media. He writes that the mausoleum is of brick, guarded by three dervishes, and visitors come there every day for relief from diseases; cures are by no means rare among them.

Prizes for Essays.—The *Medical Mirror* of St. Louis offers $1,000 in prizes, to be distributed as follows: $500, $200 and $100, and four prizes of $50 each. Entries close Oct. 1, 1900, and the award is made Jan. 1, 1901, giving the contestants three months in which to prepare their papers and to include clinical reports.

Centenarians.—According to the *Indian Medical Record,* more people over one hundred years old are found in mild climates than in the higher latitudes. According to the last German census, in a population of 55,000,000, only 78 have passed the hundredth year. France, with a population of 40,000,000 has 213 centenarians. In England there are 146; in Ireland, 578; in Scotland, 46; in Sweden, 10; in Norway, 23; in Belgium, 5; in Denmark, 2; and in Switzerland none. Spain with a population of 18,000,000 has 401 persons over one hundred years of age. Of the 2,250,000 inhabitants of Servia, 575 have passed the century mark. It is said that the oldest person living is Bruno Cotrim, born in Africa and now living in Rio de Janeiro. He is 150 years old. A coachman in Moscow has lived for 140 years.

Individual Signs of Pregnancy.—O. Naegele has observed that women who have previously suffered from phlebitis or thrombosis of the veins of the lower limbs, especially in the saphena, have a prompt and reliable pregnancy-barometer in their varix. Some multiparæ can affirm their pregnancy in eight days after conception from the condition of their varix. Women who have had puerperal complications with exudates and formation of adhesions, frequently experience a revival of symptoms at these points immediately after conception, the *locus minoris resistentiæ* proving an index of pregnancy. In two cases a thrush formation was noted on the external genitals, causing pain on urinating. He concludes his article in the *Muench. Med. Woch.*, of June 12, calling attention to the valvular formation at the external orifice of the urethra in women, which forms a right-angled closure with a slit in the middle. It is most pronounced in virgins and in persons who have never masturbated.

Causes of Typhoid Fever in South Africa.—The appalling amount of typhoid fever among the British army in South Africa is accounted for by a writer at the seat of war, in the *British Medical Journal,* July 7. He says that the alarming prevalence of typhoid fever among young soldiers and civilians in the far East is well recognized, but it is not so generally known that the disease prevails in a like manner among young emigrants to South Africa during the first two or three years after their arrival until they become immune like the older residents. South Africa is a country with a somewhat peculiar water-supply, living springs are scarce, the water channels are receptacles of all the drainage and refuse and in the neighborhood of the settlements, are used by the natives as privies, and the sanitary arrangements and drinking-water supply of the Dutch villages is generally bad. Besides this ready facility for taking waterborne typhoid, the chance of the aerial dissemination of the germs by the dust storms is to be considered and this is generally credited as an important factor by the South African practitioners. The fact that typhoid did not apparently develop among the British troops during the long voyage from England also supports the view that it is, as it occurs among them, entirely a South African product. The association of large bodies of men together in camps seems from our own Spanish-American war experience to be a very important favoring factor in the spread of typhoid, and it is probable that some of [illegible] errors [illegible] amp sani[illegible] from which our troops suf[illegible] also to [illegible] extent at the Cape.

Plague in Manila.—Capt. John S. Kulp, asst.-surgeon, U. S. A., in command of Hospital No. 3, Manila, reported May 21, 1900, that at 2 p. m., May 18, a teamster belonging to the quartermaster's department was admitted into his hospital in a semi-comatose condition, temperature 103, face flushed, but without apparent adenitis. His temperature rose to 104.5, with stuporous delirium. Examination of the blood was negative for malaria, but showed marked leucocytosis. Under quinin he improved steadily. As a tenderness in the right inguinal region was afterward noted, a member of the Board of Health was summoned, and, upon his recommendation, the patient was removed to the plague hospital, where he died at 4 a. m., May 21. The ward in Hospital No. 3, in which the case was treated, was isolated and all precautions were taken to prevent infection. Next day the chief surgeon, Division of the Philippines, issued the following circular of instructions to the commanding officers of all Manila hospitals except the Corregidor Hospital, on the island of that name, near the entrance to the bay:

> In view of the possible occurrence of bubonic plague among the white population, especially civilian employes of the government, you are directed to prepare and place on the grounds occupied by the hospital, where it may be completely isolated, a hospital tent into which all cases of fever among civilian employees, who may apply for hospital accommodation, shall be placed and detained until a diagnosis is made. Blood examinations should be made at once in all these cases. If a case is determined to be one of bubonic plague or there is good reason to suspect it, the Board of Health should be promptly notified by special messenger and the patient transferred to its care. Arrangements have been made by the Board for the care of both suspected and defined cases of this disease. The Board will also give directions for or personally superintend the sterilization of the ward, clothing, etc., in the event of a case occurring within the hospital, and will direct the necessary quarantine regulations, which must be strictly followed.

Yellow Fever in Havana.—Major W. C. Gorgas, surgeon, U. S. A., chief sanitary officer of the city of Havana, Cuba, has filed in the office of the Surgeon-General a table of the mortality from yellow fever for citizens and soldiers by months from January, 1890, till May 31. From this table it is seen that the large mortality in 1896 and 1897 was caused by the ravages of the disease among the non-immune Spanish soldiers of the garrison. In 1896 there were 1153 deaths of soldiers and only 129 of civilians, and in the following year 813 of soldiers and only 45 of civilians. In 1898 111 soldiers and only 25 civilians died. The civilian deaths during these years were few as compared with the losses suffered by the Spanish garrison. In 1899, however, during the occupation of the city by United States troops this was reversed; 92 civilians died and only 11 soldiers. Major Gorgas considers it creditable to the army medical corps that the deaths among the troops during this year were so few while so many civilians lost their lives. Up to the time the volunteers left there were in and about Havana over 20,000 troops, and although at the present time there are more than 1000 men within the city limits occupying four or five old Spanish posts, no death from yellow fever has occurred among them during the present year. The great fatality of yellow fever among the Spanish troops was the result of a want of knowledge on the part of their military surgeons of the methods of care and prevention. Their garrisons appear to have been left where they were until the disease had spent itself by using up all those who were not immune. The method of moving the troops from the infected locality, so successfully carried out by American military surgeons, does not seem to have been practiced by the Spanish authorities.

Yellow Fever Among Troops at Santa Clara, Cuba.—Chief Surgeon Valery Harvard, Division of Cuba, reported, June 26, 1900, the results of a medical and sanitary inspection of posts made by him with a view to determine the status of yellow fever in the commands. He found Matanzas, Cardenas and Puerto Caballo free from fever, but at Santa Clara a case was discovered on May 16, and since then thirty-three cases have been reported; 1 medical officer (Dr. Wheate), 27 enlisted men, and 5 quartermaster's employees. Six of the enlisted men belonged to the hospital corps. So far seven deaths have occurred. The first three cases were clearly traceable to the houses in which the men lived, near the barracks, houses in which many cases were treated in 1898. Subsequent cases were contracted from these first cases, from other infected houses and possibly from the barracks. Although it is probable that the barracks are infected, the fact can not be positively established. Dr. Wheate and the hospital corps men contracted the disease while caring for the sick. The command left the post on June 1 and moved into camp four or five miles out of town. No new cases occurred after June 6. The command returned to the barracks on June 10, but on June 15, and subsequent days, the occurrence of new cases necessitated a return to camp on June 18. As cases continued to occur in the camp after June 23, it was decided to bring each company separately to the barracks to undergo disinfection prior to removal to a permanent camp.

A virulent epidemic of yellow fever prevailed in Santa Clara in 1898, during which 1400 persons died, half of whom were civilians and half soldiers. The inference is therefore warranted that many houses and probably also parts of the barracks are still infected, although the latter were thoroughly overhauled and disinfected prior to occupation by our troops. Major Havard considers that, were the troops to return to town, under the circumstances, they would be a constant and easy prey to the contagion. He therefore recommended their continuance in camp until November. It is worthy of note that up to the date of Dr. Havard's report, not a single case had been reported among the inhabitants of the town, showing how thorough had been the immunizing process of the epidemic of 1898.

Resuscitation by Manual Compression of the Heart.—Tuffier calls upon surgeons who witness accidents from the use of anesthetics to make a special study of this subject, to determine the length of time that must elapse before manual compression of the heart becomes the last resort. He reported a case May 28, at the Académie des Sciences, in which he succeeded in restoring arterial pulsation after apparent death of a young man from syncope, four days after appendectomy. The pulsations ceased in a few minutes but were re-established three times in succession, when the only sign of life was a fibrillary trembling in the heart. Sixty to eighty compressions were made of the ventricular mass, through an incision in the third intercostal space, combined with rhythmic tractions of the tongue. The autopsy showed a clot in the pulmonary artery which had prevented permanent resuscitation.

Concentration of Serum in Uremia.—Lindemann publishes (*Deutsch. Arch f. Klin. Med.*, lxv, 1 and 2) the conclusions of extensive research regarding the concentration of the urine and of the blood in renal affections. He finds that uremia is constantly accompanied by increased concentration of the serum, and consequently increased osmotic pressure. The retention in the organism of the neutral salts is sufficient to cause this syndrome, without the necessity of the presence of any special toxic substances.

Official Commendation of Sanitary Work in Porto Rico.—On June 28, the War Department received from Gen. Geo. W. Davis, commanding the Department of Porto Rico, a special report concerning the conditions that have grown out of the efforts of the United States to relieve the suffering and destitution among the people of that island. It concludes as follows:

> A summary of the conditions in Porto Rico would be incomplete without a reference to the improvement in sanitation and health which has been effected under the supervision of United States officers. At the time of our occupation the prevalence of smallpox was so general that quarantine was declared in the neighboring islands against the seaports. The disease existed in every direction and was a constant menace to the people and the material interests of the island. A general vaccination of the whole population was systematically carried into effect, the vaccin being provided from a farm established at Coamo Springs. This extensive work was finished June 30, 1899. The disease was suppressed. No death from smallpox has been reported in the island for the past eight months. Again, while much of the emaciation and weakness ending in anemia and death so prevalent among the native population is certainly due to an impoverished diet of rice, beans, a little dried fish and plantation fruits, it has

been shown by assistant-surgeon B. K. Ashford, a recent graduate of the Army Medical School, that a great deal of the prostrating diarrhea and progressive emaciation, which has usually a fatal ending, is due to the irritating presence in the intestines of a number of minute worms, which can be easily got rid of by appropriate medication. This disease has been extremely fatal, but its ravages will now be controlled under the supervision of local boards of health. These boards, acting under the instructions of the supreme board at San Juan, have done much to improve sanitary conditions and lessen sickness and mortality among this poverty-stricken people.

The Proposed North American Medical Association.—We understand that a number of representative men among our Canadian brethren have expressed their readiness to enter the American Medical Association in case membership in that body were accorded to them, and that Dr. Reed, the newly elected president of the Association, favors their admission. We see no reason why the profession in the two countries should not have a common organization, and we think many advantages would result from its establishment. Such a body would be a North American association, whatever its name might be. Useful as the Pan-American Medical Congress has been and promises to be, it must always, after all, have the inconveniences that are inseparable from a confusion of tongues and from the meetings occurring at long intervals. Moreover, its particular field would not be encroached upon by an association of the physicians of the United States and Canada. The Canadians are more like ourselves than they are like their kindred beyond the sea—not, perhaps, politically, but in their daily life. So far as we have observed, they speak the English language as we speak it; they use a currency that is practically identical with ours; their pursuits in the main are ours; in short, they live as we live. Nowhere on earth is there a people more congenial to us than the people of Canada. The patients of the Canadian physicians are men, women and children of the same general stamp, with the same varieties, as our own; the diseases prevalent in Canada are those that prevail in the United States, and the differences between the United States Pharmacopeia and the British Pharmacopeia are so slight that when a Canadian physician mentions a British official preparation there is to us no obscurity as to what he means, and vice versa. We believe, therefore, that there would be much profit from joint discussions by representatives of the two countries.

Our national special societies, several of them, have Canadian members, and nothing but benefit has resulted from the fact. Indeed, if we are not mistaken, one of those societies has held an annual meeting in Canada. Several of the Canadian cities are quite capable of accommodating large conventions, and an occasional meeting in Montreal, Toronto or Quebec would be in the highest degree enjoyable. There are, of course, matters connected with medical registration and the like that a body drawing its members from the two countries might find it awkward to deal with so far as action was concerned, but joint discussions of even such affairs would naturally familiarize the profession of each country more and more with the problems encountered by that of the other, and so strengthen the bond of sympathy, already a close one. We hope that a way will be found to provide for annual meetings of representatives of the medical profession of the whole of North America.—*New York Medical Journal.*

Book Notices.

A Handbook for Nurses. By J. K. Watson, M.D., Late House-Surgeon Essex and Colchester Hospital. American Edition under the supervision of A. A. Stevens, A.M., M.D., Professor of Pathology in the Woman's Medical College of Pennsylvania. Cloth. Pp. 413. Price, $1.50. Philadelphia: W. B. Saunders. 1900.

This production of the American Edition of Watson's Handbook for Nurses, which has taken the place of a standard work on the subject in Great Britain, hardly needs an apology, as the editor states in his preface. The only point that we should make against it for the use of the average nurse is that it is almost too full, but this objection is probably hardly a valid one. The intelligent nurse will find this a most convenient manual, and there are many things in it that the physician himself might find of use. In recommending text-books to nurses it could be put in the first rank.

The Ophthalmic Patient. A Manual of Therapeutics and Nursing in Eye Disease. By Percy Fridenberg, M.D., Ophthalmic Surgeon to Randall's Island and Infants' Hospitals. Cloth. Pp. 311. Price, $1.50. New York: The MacMillan Co. 1900.

This volume is a sort of manual for ophthalmic nursing and also a convenient one for the practitioner who may have to do with eye cases. In fact, it is rather a physician's book than a nurse's, and should be useful to a large class. It does not do away with the necessity of a skilled specialist in the treatment of serious eye disorders, but it will come very convenient to the practitioner who may have the after-care of a case that has been in his hands.

Elements of Clinical Bacteriology for Physicians and Students. By Ernst Levy, M.D., Professor in the University of Strasburg, i. E., and Felix Klemperer, Privat-Docent in the University of Strasburg, i. E. Second Enlarged and Revised Edition. Authorized Translation by Augustus A. Eshner, M.D., Professor of Clinical Medicine in the Philadelphia Polyclinic. Cloth. Pp. 441. Price $2.50. Philadelphia: W. B. Saunders. 1900.

The translation of this work into the English language is a service to American readers. It has been well done, and the printing and make-up of the work are all that could be asked. If Dr. Eshner had added some personal notes to bring it more fullly up to our more recent knowledge in one or two points it would have been an addition, but this is all the criticism that we venture to offer.

Progressive Medicine. A Quarterly Digest of Advantages, Discoveries and Improvements in the Medical and Surgical Sciences. Edited by Hobart A. Hare, M.D., Professor of Therapeutics and Materia Medica in the Jefferson Medical College, Philadelphia; Assisted by Charles A. Holder, M.D., Assistant Demonstrator of Therapeutics in the Jefferson Medical College. Volume II. June, 1900. Cloth. Pp. 411. Price, $2.50. Philadelphia and New York: Lea Brothers & Co.

This second volume for the year contains four articles: Surgery of the Abdomen. Including Hernia, by William B. Coley, M.D.; Gynecology, by John G. Clark, M.D.; Diseases of the Blood, Diathetic and Metabolic Diseases; Diseases of the Glandular and Lymphatic System, by Alfred Stengel, M.D., and Ophthalmology, by Edward Jackson, M.D. All of these seem to be very excellent summaries of the principal progress that has been made within a recent period on their respective subjects, and it would be invidious to mention one as better than the other. In fact, the special excellencies and defects of the treatment of each of these subjects can be best appreciated only by the specialist. To the average practitioner the work will be a valuable one, and all that could be expected or asked.

Suggestions to Medical Writers. By George M. Gould, A.M., M.D. Cloth. Pp. 185. Price, $1.25. Philadelphia: The Philadelphia Medical Publishing Co. 1900.

This little volume is largely made up of papers or editorials that have appeared in the *Philadelphia Medical Journal*, and which bear the characteristic stamp of the personality of the brilliant author. The tyro in medical writing and the more or less practiced and careless writer for the journals, and even in books, and these include the majority, will find many things in it which will be of value. The author has covered the use of words, orthography, punctuation, titles, medical English style, and has also laid down the rules which he thinks editors and publishers should follow. There is, of course, in this as in all other reforms, a personal equation of the advocate, and some may not follow Dr. Gould in every particular. Common sense must govern all the changes which are advocated, and too rigid following of any rule may be found inconvenient. There are also differences in the matters of personal taste, and a certain margin must be allowed, unless the writer goes so far in his views and in his practice as to become like some rigid literary purists that lean backward and lose the grace that the easier movement would give. Sometimes in reading a book like this we are just a little reminded of the man who was down on superstitions because, as he said, whenever he followed one he always had bad luck. In the chapter on medical paleography there is a large amount of interesting antiquarian knowledge which will be new to the majority of readers. The work, as might be expected, is interestingly written, and few who take it up will lay it down without finishing its perusal. It will also be a very handy book of reference and will certainly be of great convenience to editors as well as to readers, if the great majority of advice given is followed.

The Cell in Development and Inheritance. By Edmund B. Wilson, Ph.D., Professor of Zoölogy, Columbia University. Second Edition. Revised and Enlarged. Cloth. Pp. 483. Price, $3.50. New York: The MacMillan Co. 1900.

While the early edition of Professor Wilson's work was criticized by biologists, in some respects it has nevertheless stood as a leading contribution to its subject. In this second edition the author has completely revised it, rewriting entirely certain sections and making minor changes, as he says, on nearly every page. In a progressive science like biology, in which so many active workers are in the field, a second edition of a work is required almost as soon as the first one is issued, hence the importance of the additions as given here. In his generally conservative method of viewing certain questions Professor Wilson is a safer guide than many who hasten to interpret facts which must necessarily be incomplete, and his standpoint in regard to many disputed questions in regard to vital processes is one that can be, as a rule, safely commended. The book has been enlarged by the addition of some fifty new cuts, which usefully illustrate the text. Its subject is one that interests every cultured individual, and especially physicians, who will find in this volume many things easy for reference which would not be so readily available elsewhere.

Twentieth Century Practice. An International Encyclopedia of Modern Medical Science by Leading Authorities of Europe and America. Edited by Thomas L. Stedman, M.D., New York City. In Twenty Volumes. Volume XIX. Cloth. Pp. 828. Price, $5.00. New York: William Wood & Co. 1900.

The next to the final volume of the series contains simply two subjects: Malaria and Micro-organisms. The first of these, by the Italian authors, Bignami and Marchiafava, who have done so much to elucidate the problems of malaria, comprises not less than 500 pages—including the bibliography, 522 altogether. There is probably no monographic work on the subject that is more thorough than this and it will stand for some time as a leading compend of its subject. It seems, with the numerous questions still to be solved that an attempt at an exhaustive memoir would be premature, but this comes as near to one as possible with our present knowledge. The second section of the work, comprising the last 300 pages or more, covers the general subject of micro-organisms as met with in disease, including their classification, metabolic products, the technique of bacteriology and specific descriptions. The first and larger part of this is by Prof. Simon Flexner, of Philadelphia, whose name should be a guarantee of thorough work and of the value of his memoir. The second, covering the animal micro-organisms that are of pathologic importance, by Eugene L Opie, comprises 40 or 50 pages, and gives a very fair general statement of the facts as known, and both together form a very convenient and well-arranged general manual of pathologic bacteriology. The volume as a whole will rank as one of the most useful of the series—perhaps the more so since it comprises only two monographic works.

Tuberculosis: Its Nature, Prevention, and Treatment, with Reference to the Open-Air Treatment of Phthisis. By Alfred Hillier, B.A., M.D., C.M., Fellow of the Royal Medico-Chirurgical Society, London. Thirty-one illustrations and three colored plates. Cloth. Pp. 243. Price, $1.25. London, Paris, New York and Melbourne. Cassell & Co., Ltd. 1900.

The subject of most general interest at the present time before the profession is undoubtedly tuberculosis, therefore this little work is in its way timely. The author gives the generally accepted views of the disease, its methods of dissemination, and its cure. He admits that immunity from tuberculosis is to be derived mainly through good sanitation, light and air, and all that is conducive to the general moral and physical welfare of the masses of the people. He accepts fully the opinions that tuberculosis is largely spread through the agency of foods, although there may be some question about that, or at least there is a possibility of a difference of opinion, which he does not fully recognize, as to the importance of bovine tuberculosis. Compulsory notification is discussed, but not fully advocated, although the author thinks that the time will come when, as the public is educated as to the true nature of tuberculosis, notification and supervision will be insisted upon, as he seems to think that theoretically they should be.

A Cyclopedia of Practical Medicine and Surgery. A Concise Reference Book, Alphabetically Arranged, of Medicine, Surgery, Obstetrics, Materia Medica, Therapeutics, and the Various Specialties. Compiled under the editorial supervision of George M. Gould, M.D., and Walter L. Pyle, M.D. Quarto. Illustrated. Sheep or Half Dark-Green Leather. Price, $10. Philadelphia: P. Blakiston's Son & Co. 1900.

With the ever-increasing number of monographs, elaborate treatises on individual subjects, text-books of many volumes, and long-drawn-out original articles in medical journals, it seems a relief to pick up this work, in which is found, in a condensed form, the accumulated medical knowledge of the day. While seventy-four names are given in the list of contributors, there is a uniformity of style and method that is commendable. One criticism of books produced by the collaboration of so many authors is that the reader is likely to be bewildered by a heterogeneous mass of material, repetitions and contradictions. This criticism, however, does not apply here, as the individual style of the many has been eliminated by editorial revision, and as repetition has been avoided by the exclusion of all that might tend to redundancy. As indicated in the title, every branch of medicine is covered and a careful examination fails to reveal the omission of a single subject of importance. Each topic is treated in a practical manner, with the aim to make the work of practical use to practical men in active work. In the consideration of diseases, diagnosis and treatment are made paramount, and under the latter many tried and reliable prescriptions are given. The book is fairly well illustrated. As a practical hand-book for every-day reference, this work can be heartily indorsed and conscientiously recommended.

A Manual of Obstetrics. By A. F. A. King, A.M., M.D., Professor of Obstetrics and Diseases of Women and Children in the Medical Department of the Columbian University, Washington, D. C. Eighth edition, revised and enlarged, with 204 illustrations. Cloth. Pp. 612. Price, $2.50. Philadelphia and New York: Lea Brothers & Co. 1900.

King's Obstetrics has made an enviable name for itself, that of being one of the most compact and complete of manuals on midwifery. The fact that another edition has been called for proves that the book has retained its well-earned reputation. It is brought thoroughly up-to-date in all its departments, and the newest remedies and latest obstetrical operations are considered. There are a large number of new illustrations, which, added to those which appeared in the previous editions, makes the volume one of the best illustrated manuals on obstetrics. It is worthy of earnest commendation.

New Instrument.

Sterilizer.

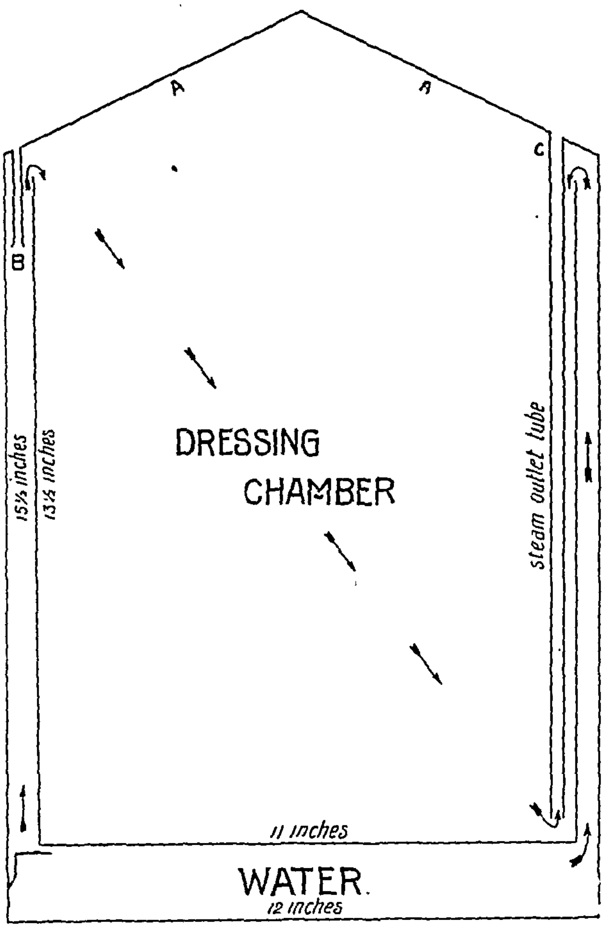
E. DIKO, M.D.

PARK CITY, UTAH.

My only excuse for offering this sterilizer is because it is simple—any tinsmith can make it—cheap, and planned on the principles of ideal sterilization. It may be made of copper, galvanized iron, or other metal. It consists of two cylinders with buttons. The outer cylinder is 15½ inches high by 12 inches in diameter, and a small faucet is put as close to the bottom as possible. The inner cylinder is 13½ inches high by

11 inches in diameter; it rests on three or four small brackets or catches attached to the inside of the outer cylinder, about 1½ inches from the bottom, or three or four legs, 1½ inches high, might be attached to the inner cylinder.

The cover is slightly conical in order to prevent any condensed water, which may collect on its under surface, from dropping into the dressing chamber. This cover has two openings, to which are soldered two tubes—"a" and "b"—each about the size of the end of the middle finger. Tube "a" is 2 or 3 inches long, and is attached close to the outer edge of the lid. Tube "b" is attached to the lid, so that it will rest close to the inner side of the inner cylinder. It extends within one-half an inch of the bottom of the inner cylinder. Four clasps, to hold the cover firmly in place, may be attached to the outside at the upper edge of the outer cylinder. A heavy wire cross, with legs ¾ inch high, may be lowered into the inner cylinder in order to obtain a better circulation in the dressing chamber, and to this a handle may be attached.



A A Lid B Tube C Outlet Tube

In order to use this apparatus pour into the outer cylinder from one-half to three pints of water, lower the inner cylinder, fill it with the dressings to be sterilized, put on the cover, and in so doing slip the long tube of the cover into the inner cylinder, but the short tube between the inner and the outer cylinders. Close the short tube "b" with a cork, but leave the long tube "c" uncorked. The steam created in the outer cylinder will enter the inner cylinder from the top and, after going down though the dressings, will escape by the long tube. When sterilization is nearly at an end remove the cork from the short tube in order to thoroughly dry the dressings. If it is desired to follow Schimmelbusch's method exactly, tube "b" is first left uncorked and tube "c" corked up for a short time until the dressings are warmed, then tube "b" is corked and tube "c" uncorked. Finally tube "b" is uncorked. The shorter tube "b" serves three purposes: Water can be poured in through this, as desired, during the sterilization; it serves as an exhaust for steam when the dressings are being warmed at the beginning of the process; also, it is a steam-exhaust at the close of sterilization, when the dressings are to be dried. The long tube acts as a steam outlet during the active sterilization. The faucet serves two purposes; by opening during the process it will show whether more water is needed, and at any time hot water may be withdrawn.

I have used this sterilizer for two years with entire satisfaction. A temperature of 300 F. may be easily obtained and maintained.

Societies.

German Ophthalmological Society.—This Society will meet in Heidelberg, Sept. 13-15.

Dallas District Clinical Society.—This Society met in Dallas, Texas, July 4. The following officers were elected for the coming year: president, J. T. Benbrook, Rockwall; first vice-president, C. A. Schultz; Alvarado; second vice-president, B. F. Brittain, Arlington; secretary, J. B. Shelmire, Dallas; treasurer, J. E. Baldwin, Reinhardt.

Medico-Psychological Society.—This Society held its fifth semi-annual meeting at the Protestant Hospital for the Insane, Verdun, P. Q., June 27. The object of this Association is the interchange of experiences and the development of mutual co-operation among the medical men connected with the several institutions for the care of those mentally afflicted in that province. There were present Dr. T. J. W. Burgess, Montreal, the retiring president; Dr. G. Villeneuve, Montreal, vice-president; Dr. E. P. Chagnon, Montreal, secretary; and Drs. L. U. A. Bellanger, Beauport; J. V. Anglin, Montreal, and C. A. Perrault, Montreal. Papers were read by Drs. Anglin and Chagnon. Dr. Villeneuve made some interesting observations concerning the relations between the legal and the medical professions, regarding the incarcerating of inmates in the asylums. Dr. Chagnon suggested that a special committee should arrange a scheme for uniformity in the tabulation and classification of statistics by the several asylums in the Province of Quebec, a suggestion which was heartily commended and unanimously adopted. Dr. Villeneuve was elected president, and Dr. Bellanger, vice-president; Dr. Chagnon being re-elected secretary. The next meeting will be held at the Beauport Asylum, in October.

Chicago Academy of Medicine.

April, 13, 1900.

CARCINOMA OF THE COLON.

Dr. Paul F. Morf reported the following: A boiler-maker, American, aged 59 years, was admitted to the Policlinic Hospital Feb. 15, 1900, in the service of Dr. Halstead. The family, personal and previous history were negative.

The patient's illness began somewhat insidiously, in September 1898, with more or less intermittent sharp and lancinating pain, coming on after eating. These pains had continued up to six weeks before his admission to the hospital, but since then have been less severe. About September, 1899, he noticed a tumor in the abdomen, on a level with and somewhat to the right of the umbilicus, which increased in size during the next four months, and then apparently remained stationary. About the time the tumor was noticed, he began to have trouble with his bowels, which moved with difficulty, laxatives being necessary to produce satisfactory evacuations. At no time was there absolute obstipation or symptoms of complete intestinal obstruction. There had been no passage of blood with the feces, nor has the patient noticed that the fecal masses had any unusual shape. Since the beginning of his illness he has lost between fifteen and twenty pounds in weight, and eats little, on account of the distress which follows. His sleep is disturbed.

On admission to the hospital, physical
the patient to be well built and well dev
above the average height. The general
ately good, no decided emaciation, but
oped panniculus adiposus was present.
anemia, evidenced by the pale, yello

of the skin, and a decided pallor of the mucous membranes of the lips and tongue. The pulse was small, compressible, of about 88 to 90 beats per minute, and there was a moderate increase in frequency of the respirations. The temperature was normal. Inspection showed the anterior abdominal wall to be somewhat retracted, and on the right side, a little above the level of the umbilicus, a very slight prominence could be seen, which shaded off imperceptibly into the surrounding parts. On palpation, a firm non-fluctuating tumor the size of a medium-sized orange, could be felt. It was moderately tender, did not rise and fall with the respiratory movements of the abdominal wall, and was relatively immobile. On light percussion, the tumor gave relative dulness, while on heavy percussion, a muffled tympany could be elicited. The stomach, after being distended with sodium bicarbonate and tartaric acid, could be seen to lie above and to the left of the tumor; percussion showed that the greater curvature was above the plane of the umbilicus. It did not appear to have any connection whatever with the tumor, nor did the distension alter in any way the position or relations of the latter. Inflation of the colon with air caused the tumor to ascend slightly, which indicated that it was located at the hepatic flexure, but did not cause the colon to pass in front of the tumor and replace by tympany the area of dulness previously mapped out. Percussion of the liver showed the normal upper and lower borders of dulness, the lower border of the liver dulness, however, gradually merged into the relative dulness of the tumor in the right mammary line. The spleen and kidneys could not be palpated; the surface of the liver in contact with the abdominal wall showed no nodules, but was perfectly smooth. The superficial lymphatic glands were not enlarged. The urine was normal.

From the point of view of diagnosis the following conditions had to be considered:

1. Cancer of the pylorus, which was excluded by the absence of symptoms of pyloric obstruction, the normal size of the stomach, and the absence of signs—after distending the stomach—which point toward an intimate connection between the stomach and the tumor.

2. Carcinoma, or cystic enlargement of the gall-bladder, with adhesions to the anterior abdominal wall and colon. The absence of hepatic colic, of jaundice, and of any evidence of metastases in the liver, made this diagnosis seem unjustifiable.

3. Tumor of the mesentery was excluded by considering the infrequency, motility, shape and size of this variety of tumor, and also from the fact that they usually lie internal to the colon and not in its path.

4. Carcinoma of the hepatic flexure of the colon was thought to be the pathologic condition present from the clinical history of intermittent partial obstruction to the fecal current, and the physical signs which the tumor presented.

Operation on February 16, verified the diagnosis of cancer of the hepatic flexure by the finding of a nodular tumor, about as large as the fist, connected with the colon and bound down to the postero-lateral abdominal wall by numerous firm fibrous adhesions. The impossibility of complete removal of the neoplasm was evident at once, and instead of the radical operation palliative measures were adopted, a lateral anastomosis of the ascending to the transverse colon being made. A Frank's coupler was used, the union of the adjacent serous surfaces being further insured by an *étage* of sero-serous sutures. The incision was closed without drainage. The patient made a good recovery, and left the hospital March 18, 1900.

This case presents some features of interest.

1. The moderate amount of functional disturbance which a cancer of the large intestine may cause, even when it has so developed that removal is no longer possible.

2. The value of inflation of the colon with air in order to determine the relation of an abdominal tumor to the peritoneal plates which support the colon.

3. The ability to say positively before opening the abdominal cavity whether or not a complete removal of a cancer of the large intestines will be possible. Firm fixation of the growth in this are would seem to indicate, as in cases of cancer of the rectum, that radical operation is impossible.

4. The treatment to be adopted when the radical operation is impossible. In this case the difficulties from which the patient suffered were mainly obstructive. Consequently, a lateral anastomosis effected a symptomatic cure and at the same time was the operation of least danger to the patient. Had the principal symptoms been those which follow disintegration and breaking down of the tumor, namely, septic absorption, suppuration and hemorrhage, it would have been desirable to prevent any contact of fecal matter with the ulcerating surface, by making a typical exclusion of the intestine. This, however, is an operation of greater magnitude than the one which was performed, and had it been done, nothing would have been gained as regards the results. On the contrary, the patient would have been subjected to the inconveniences which inevitably result when the intestine discharges its contents and secretions on the surface of the body.

Dr. Alexander Hugh Ferguson referred to a clamp and enterotome which he had devised to facilitate intestinal anastomosis, which he had used in two cases in the human subject. His objection to the application of buttons or couplers, or in fact of any mechanical device, is that in making an anastomosis of the large bowel a small lumen is left.

Dr. Jacob Frank said that his coupler or the Murphy button leaves a much larger lumen than most surgeons imagine, because the pressure that is extended upon the ends of the intestine is practically done away with.

Dr. A. E. Halstead said he was not in the habit of using the Frank coupler or Murphy button. As to the relative value of the coupler and the Murphy button, the latter is easier of application, although an objection to the Murphy button is that it can not be absorbed, and there is more or less risk attending its use. In his intestinal work he invariably used the suture method, although he was gratified with the result obtained in this case by the Frank coupler.

Dr. William A. Evans said he had examined a moderate number of intestines after the use of both the Frank coupler and the Murphy button, and believes that the danger from stricture from the use of these mechanical devices is more imaginary than real, and that there is not very much danger from secondary contraction following operations on the intestinal walls. Histologically the bowels that have been operated on indicate that the contraction of the cicatricial fibers is not circular. The only fiber that is responsible for secondary contraction or stricture is the connective-tissue fiber which runs in a circular direction.

GUNSHOT WOUNDS OF THE BLADDER.

Dr. Carl H. Anderson reported an interesting case of this kind, and, after an exhaustive review of 315 other cases which he had found in the literature, drew the following conclusions:

Intraperitoneal Wounds.—1. The mortality in intraperitoneal bullet-wounds of the bladder is very high, and due almost exclusively to peritonitis.

2. It appears that shock or hemorrhage did not materially contribute to the death-rate or it would have been mentioned, but it was probably overlooked.

3. The fact that before the antiseptic era, all of the 30 patients died, and since that time only two out of four are living, and that these two were the only ones treated by laparotomy, rather clearly indicates what should be done.

2. *Extraperitoneal Wounds.*—1. The mortality of extraperitoneal vesical injuries due to bullets is only 13.4 per cent. and peritonitis is not mentioned in this connection.

2. Extravasation of urine was the main cause of death. A few died from hemorrhage and several from prolonged suppuration.

3. Permanent fistula was a frequent sequela, especially when the rectum was involved. No operation has been done for the rectovesical fistula.

4. It should be pointed out that since 1873, 10 patients have been reported as treated antiseptically, and all lived.

3. *Treatment.*—The author's thinks that emphasis should be laid upon the following:

1. Shock was extreme in his case. He advises that while preparations are being made for further treatment, this should be attended to. In addition to the administration of stimulants, etc., salt solution at a temperature of 135 F. thrown into

the rectum immediately improves the condition by the heat, which powerfully stimulates the vasomotor innovation of the alimentary and portal circulation, which in turn increases the heart action and improves the general nervous condition. He has verified this effect of hot rectal injections on dogs suffering from experimental shock.

2. If shock is due to hemorrhage, intravenous or intracellular transfusion is preferable.

3. In extraperitoneal wounds of the bladder the indications are to insure at the earliest possible moment complete and free drainage of urine from the bladder and thus to prevent infiltration and infection of the paravesicular connective tissue in the lesser pelvis. At the very outset, therefore, measures should be taken to explore the original wound and, by means of proper drainage, to insure free escape of urine. This should be supplemented by permanent catheterization or perineal cystotomy. In cases in which urinary infiltration has already taken place, the infected tissues should be irrigated and drained as thoroughly as possible.

4. As nearly all, if not all, cases of intraperitoneal vesical bullet-wounds terminate fatally, if not operated on, we are justified in opening the abdomen in every case. Delay should never be advised. If urine is found in Douglas' pouch it should be mopped out. The bullet-wound should be searched for, and if the bullet is located in the bladder it should be removed through this wound; which is then sutured with Lembert's sutures, the peritoneal cavity flushed out with salt solution at a temperature of not less than 115 nor above 120 F. until the cavity is clean and a drainage-tube inserted. Before the patient leaves the operating-table, the bladder should be cleansed and a good-sized rubber catheter passed into it through the urethra to insure thorough drainage of the urine, and vesical rest. Perineal section and drainage will efficiently keep the bladder empty, but the additional traumatism caused and time consumed thereby should be considered as bearing adversely upon the immediate safety of the patient.

5. While primary laparotomy aims at preventing peritonitis, it may not always do so, inasmuch as the abdomen may not be opened until one, two, or three days after the injury, and peritonitis is well established. It is rare indeed for any patient with septic peritonitis to recover. It is incumbent upon the surgeon therefore to perform a laparotomy even when peritonitis is unmistakable; to cleanse the peritoneal cavity of all perceptible inflammatory products and to drain thoroughly. In this connection a distinction must be made between intraperitoneal irrigation and flushing. The former does harm by causing absorption of the deadly elements, while the latter removes them. The quantity and temperature of the salt solution to be used are important. He employs about 35 gallons at a temperature of 116 F. When the abdominal toilet has been completed, and the source of danger thereby cut short, intravenous transfusion should be resorted to and, if necessary, repeated several times in severe cases. Dr. Andersen also exhibited an apparatus which he had devised for normal salt transfusion in all cases.

THE ETIOLOGY OF DEFLECTED SEPTUM.

DR. J. HOMER COULTER followed with a paper on this subject, in which he argued that in many cases, though not invariably, rhinitis is the cause and not the result of a deflected septum; that simple traumatism is not the most frequent cause, but often an important factor, especially when the deflection is found in very young patients. He contended that it is not found in infancy because the turbinate prominences are not usually sufficiently developed to produce an effective stenosis, and asked if, as some claim, it be the result of hypernutrition, why do these same individuals operate before there is complete development, and yet not expect a return of the condition?

While it may be true that the cause of the condition is not thoroughly settled, nevertheless of the results both the general practitioner and specialists have frequent and abundant positive proofs. Some of these the author mentioned as: 1. Deformity of the nose and face, sometimes extending to or occurring in the chest, resulting possibly in bronchial emphysema, cough, marasmus, or even melancholia.

2. The voice frequently suffers.

3. Many cases of laryngeal and pharyngeal affections are clearly traceable to a defective nasal passage.

4. Asthmatic conditions are not infrequent, and are as well the least promising results of brilliant operations.

5. Partial deafness is not an infrequent sequel of deflected septum, as the experience of rhinologists generally will affirm.

ARTHRITIS DEFORMANS IN A CHILD.

DR. FRANK X. WALLS read a paper on this subject, of which the following is the substance:

Under the name of chronic deforming polyarthritis is grouped a promiscuous collection of diseases that have little in common save the joint involvement. This group does not include the joint affections that are dependent upon trauma or are tubercular or syphilitic, since these, though the joints may be chronically and deformedly inflamed, present such peculiarities in their history, appearance and course as to readily permit their true causative factors to be estimated.

Chronic deforming polyarthritis may be classified etiologically under three or four heads: 1, succeeding acute rheumatism; 2, sequel to the acute infectious diseases; 3, neuropathic arthritis; 4, arthritis deformans that appears to be primary or essential.

In the first group the history of acute rheumatism may be obtained if we keep in mind the often insidious and latent course that acute rheumatism pursues in childhood. These cases as a class differ from the other groups, and particularly the secondary infectious group, in that the arthritic inflammations are more mobile; they never terminate in suppuration; very frequently they are associated with lesions of the pericardium or endocardium, and they are favorably influenced by sodium salicylate.

The second group may be difficult of exclusion. During the course of any of the infectious diseases articular determinations, distinct from acute rheumatism and depending upon a general infection of the organism may occur and pursue a chronic course. In this second group there is a history of preceding infection; they more frequently terminate in suppuration: the progressive centripetal character is not so marked, and more often the larger rather than the smaller joints are involved. The neuropathic group is so rare in childhood that it need not be more than mentioned.

Garrod says that essential arthritis deformans enjoys the distinction of having been called by a larger number of different names than any other in the whole category of disease, but he prefers the name arthritis deformans, for it implies no theory and presupposes no relation to other diseases. In childhood the evolution of the disease is usually more rapid than in adults, more articulations being involved in a shorter time. The disease runs a centripetal course, beginning usually in the small joints of the fingers, hands and feet, and eventually may extend to the larger articulations. Occasionally the disease is confined to the larger articulations. When the disease is well established the hands assume a disfigured appearance, the joints are swollen, painful, rigid. Enduring deformity may ensue from changes, rarefaction succeeded by eburnation, in the bones, and sclerotic retraction of fibrous tissue. It is almost unnecessary to state that this condition of the joints renders the afflicted parts impotent. The pain is very severe, the deformities become permanent, and the child pale and cachectic. Charcot has described two classical types of deformities of the hand, the flexed and the extended. Chauffard and Ramond have observed in some cases of deforming arthritis a considerable swelling of the lymph-glands situated beneath the affected joints—*adenopathy sus articulaire*—and they consider this alteration as suspicious of the infectious nature of the chronic polyarthritis.

Heberden has described under the title of "*digitorium nodi*" little hard knobs about the size of a pea occurring in arthritis deformans, situated upon the ends of the fingers, usually over the second phalanges. Sometimes during the exacerbation of joint inflammations these nodes are tender and painful, but usually they present no other inconvenience than their unsightliness. In arthritis deformans of childhood a favorable termination after months or years is not uncommon. The joints may gradually recover their motility, bony swellings may dissolve, the deformity become less or perhaps disappear, and there may remain more or less lax condition of the joints.

In childhood the disease does not so truly merit the appellation of progressive, and even in the adult favorable terminations have been observed.

Cardiac localizations are unusual in the non-rheumatic forms.

The etiology is obscure. The diagnosis is based on the course of the disease and the readily demonstrable changes in the chondro-osseous parts of the joints, and by the presence of Heberden's nodes. The course is characterized by its exquisite chronicity and progressive character, with pain and increasing impairment of function until the joint movements in certain directions are restricted or impossible. During the acute exacerbations the disease may simulate tetanic, tubercular or syphilitic arthritis, or rheumatism, but a careful consideration of the history, character and course of the disease will be sufficient to exclude these disorders.

Treatment should be directed to improve the general condition of nutrition by supplying abundant fresh air, good food, and attention to the skin. During the acute periods we may administer salicylate of soda and antipyrin internally; we should immobilize the joints and apply locally soothing oils and ointments. In the interval, general tonics may be employed, such as cod-liver oil, iodid of iron, tincture of iodin, arsenic, alkaline and thermal baths, massage prudently employed, and galvanic electricity.

The history of the case he wished to report is as follows: The patient is a female child, 5 years old. Her father is a chronic dyspeptic; her mother, brother and sisters are well. When a baby, the child was well until the end of her first year of life. The family were then living in some dark, damp, illy-ventilated basement rooms. When one year old the child was said to be cross and irritable, but had no serious illness until she was 2 years old, when she began to complain of pain in her hands, which continued intermittently for over a year, and then extended to the feet, and later to the back. When he saw the child a year ago she had then been suffering for about two years, and the pain, the deformity, and the impotence of her hands were extreme. Examination at that time revealed a child who was very poorly nourished and ill-developed, and whose skin and visible mucous membranes were pale. Her lungs and heart were negative; her abdomen was somewhat distended with gas-inflated bowels, but no alteration in the size of the liver or spleen could be determined. The urine was negative; the cervical, axillary, cubital and inguinal lymph-glands were not enlarged. The hands were flexed and held against the chest. The metacarpophalangeal and the interphalangeal joints of both hands were much swollen, slightly reddened and extremely painful. The periarticular tissues were very much wasted, and accentuated the joint enlargement. Motion of the small joints of the hand was impossible, because of pain and fixation. Heberden's nodes were to be seen on the dorsal aspect of the phalanges as they now appear in the photograph. The wrist joints were only to a slight extent involved. An X-ray showed little osseous change, perhaps a rarefaction of the phalangeal articulation. The smaller joints of both feet were sensitive to manipulation, but were not deformed.

The lower vertebral articulations were slightly sensitive and somewhat stiffened; the other joints were negative. She had complained of some stiffness in the maxillary articulation, but when examined she was free from pain and the movements of the jaw were not restricted.

The child has been under observation for a year, and during this time the family has been living in more hygienic quarters, and the child has been receiving more wholesome food, in addition to general tonics and massage. Her general health has immeasurably improved. The deformity of the fingers is much less; the motion is so much greater that the finger can be almost fully extended; but even now the muscle atrophy and joint swelling are very evident, and mild Heberden's nodes are to be seen in the photograph taken a few days ago. Pain is present in the hands only at very rare intervals, and is not severe. The improvement in her general condition and her joint disease is so striking as to warrant the hope of a favorable termination.

AMERICAN.

1. **Uterine Fibroids.**—Richardson calls attention to the advisability of early operations in the young who suffer from uterine fibroids, so that the uterus may be saved by limiting the operation to the tumor itself. He is satisfied that early operations permit the enucleation of small fibromata in a large percentage of cases, and even in some cases of large tumors. The dangers of myomectomy are less than those of hysterectomy, and an especial point is the ability to avoid infection from the uterine cavity, which is a serious danger. He shows the possibilities of evil in the existence of fibroids as justifying operation when feasible, without, however, underestimating the dangers of intervention.

2. **Use of the Angiotribe.**—Davenport advocates the use of the angiotribe as a safe and convenient means of controlling hemorrhage, rendering the operation easier for the surgeon and much more comfortable for the patient. He thinks that it is a distinct therapeutic advance and that it has come to stay.

5. **Hemorrhagic Encephalitis.**—Dana and Schlapp report a case of hemorrhagic encephalitis occurring in a man of advanced age with alcoholic antecedents, that was apparently complicated with malaria. The condition is discussed and the article illustrated with microscopic findings.

6. **Cancriameba Macroglossa.**—Eisen describes the organism that he believes he has isolated in cases of cancer, to which he gives the above name, and which he thinks identical with that of Plimmer. He claims that it is found in all epithelial carcinomata and is the cause of the characteristic structure of the cell nests or cell plugs. These are due to the efforts of the epithelial cells to fence in the organism in the constant struggle going on between them. The propagation of the ameba is by spores and amitotic division. Mitotic division has not been observed excepting in epithelial cells. The cancriamebæ are nearly always surrounded by small vacuoles caused by destruction of epithelial cells by the parasites. It finally enlarges and makes a pus cavity. They are distinguished from leucocytes by their larger size, frequently exceeding 25 to 30 microns in length. A peculiarity of these is their sensitiveness to cold, which suggests a freezing treatment of carcinoma.

7. **Fistula in Ano.**—Gant believes that tuberculous fistula of the anus is secondary to pulmonary tuberculosis, which latter is rarely, if ever, secondary to it, either before or after operation. And fistula should be dealt with radically, and all fistulæ should be operated on, irrespective of the kind, if the patient's condition admits, and persons suffering from a mild form of tuberculosis, or those who give a family history of tuberculosis, should not be excluded. When death occurs after operation, he believes that it is due to inflammation of the lungs induced by the anesthetic, and that there is no truth in the belief that the operation on fistula produces pulmonary tuberculosis. He does not think that more than one in six or eight cases of fistula is due to tubercle, and he also holds that non-tuberculous fistulæ are not uncommon in tuberculous subjects.

9. **Tetanus.**—The treatment of tetanus and the nature of the infection are discussed by Lembert, who concludes that there are three indications to be followed: Speedy elimination of the poison, which can be done largely by increasing the action of the kidneys. The thirst of tetanus patients is excessive, and it is well to allow them to take as much water as they can. 2. The administration of physiologic antidotes to counteract the poison of the body cells. Chloral is the best physiologic antidote, as it diminishes the excessive excitability of the nervous system. 3. Chemical antidotes to render the virus inert. Antitoxic antiseptics can not be safely used in large doses, though he refers to Baccelli's reported cures with carbolic injections. The antitoxic treatment seems encouraging, but he has collected fifty-two cases in which the method of Roux and Borrel—intracerebral injections—was employed, and is not favorably impressed with it. He thinks, however, that, with the ordinary method freely used, the chances of recovery are better than without it, and in subacute cases they are decidedly in favor of recovery. He has no doubt that many cases of human tetanus would be preventable if prophylactic doses of 10 c.c. of antitoxin serum were more generally used. In using the serum, intravenous injections act more surely and quickly, and should be given when possible. The first dose should be 20 or 50 c.c., followed twelve hours later by 20 c.c., and every twelve or twenty-four hours afterward with 10 to 20 c.c.—for children half the dose.

10. **Immunizing Cure of Hay-Fever.**—Curtis has experimented with extracts of flowers supposed to produce hay-fever, such as golden-rod, rag-weed, etc., and claims remakable success with his experiments so far as carried on. He says that if his theory that this *rhinitis vasomotor pariodica* or *corasthma ambrosiæ* can be prevented by giving 2 to 10 drops of tincture of fluid extract of rag-weed in water, three times a day, during the two weeks before the paroxysm, is correct, he believes that he has heralded with becoming modesty what he considers to be a great discovery.

11. **Stools in Infantile Diarrhea.**—First noticing the different kinds of pathologic stools of infants, the dirty lead-colored, the green stool, the whitish or grayish one, the constipated, etc., he sums up the treatment of bowel conditions of infancy in three words: elimination; 2, disinfection; 3, feeding; always using as few drugs as possible. The first step is to stop the food for one or two days, using barley water or plain sterile water for thirst, then rid the bowel of diseased contents with dram-doses of equal parts of castor-oil and aromatic syrup of rhubarb, following this up with antiseptics, such as calomel, salol, bismuth, etc., using other methods, such as hot applications for pain, anodynes, stimulation, irrigation with normal salt solution, etc., as the case requires. The great difficulty is to find the proper food. None of the proprietary foods are satisfactory without the addition of fresh cow's milk, and often one food after another will have to be tried, until the whole scale has been run. The best, after all, is the modification of fresh cow's milk, Pasteurized, if need be, to decrease the risk of infection. Any progressive physician can work out his own percentage and instruct the mother.

12. **Intrascapular-Thoracic Amputation.**—Buchanan holds that the removal of the scapula and part of the clavicle is justified in every case of malignant tumor requiring amputation at the shoulder. The advantages of this are: more thorough and higher removal of lymphatic vessels and veins; the muscles, frequent sites of secondary infection, are also removed, and the glands and fat are more thoroughly cleared out; the wound is also better adapted for healing than is the stump containing the overhanging acromion and the retreating glenoid fossa. The difference in the resulting deformity is insignificant, and the fact that there has been recurrence in these parts which were not removed is another reason for their removal. He describes the operation, reports two cases, and publishes several pages of tables showing the history of the operation with analysis of cases reported.

14. **Rennin.**—Coriat gives the facts as regards the coagulation of milk showing that rennin is an independent enzyme distinct from pepsin, and that it possesses a different action on the solution of casein, or on casein in milk, precipitating it as a definite compound or curd. There are also enzymes in plants and bacteria that are almost identical in their action. He then speaks of his experiments to ascertain why rennin is a special enzyme when others are similarly effective, and how it contributes to the further conversion of soluble proteids. It had occurred to him that this precipitation has something to do with peptone production, and the experiments were undertaken to determine the question.

20. **Secondary Cataract.**—Bates has traced in the rabbit the formation of the connective-tissue membrane which veils the pupils after the removal of the lens, and finds that it is composed of new tissue together with the folded posterior capsule, the opacity being due to the former. The secondary cataract begins with the accumulation of coagulable blood in the anterior chamber at the time of the operation, fibrin appearing from its coagulation, and the connective tissue later replacing it. This process can be prevented in the rabbit by performing a quick operation, closing the scleral and corneal wound with sutures and restoring the anterior chamber with normal salt solution. These facts afford a strong presumption that secondary cataract in man is also due to the same process, and he is carrying on studies to determine this as far as possible.

22. **Identification of Blood.**—Birchmore says that it has been recognized for a long time that human blood can be distinguished fom that of any other animal, and claims that, by careful and numerous examinations and measurements, the blood-stain can be distinguished as belonging to the same blood as another given stain, or not so belonging. He believes that within limitations an expert can say positively that the blood-stain A is not the same as that of stain B. or he can say it is his opinion that the blood of stain A is the same as that of stain B. He admits, however, that the stains not identical are more easily and convincingly demonstrable than are the opposite.

23. **Typhoid Fever.**—Skinner reports a case differing from the average in some particulars, especially in the temperature curve. This was treated largely by catharsis, a method which has wrought results in his hand almost or quite as good as those of the Brand treatment.

28. **Tetanus.**—Stucky reports two cases in which boys were treated with large doses of Roux antitetanic serum, with success. In one case 30 c.c. were given as often as every six hours, until twelve bottles had been used; and in another, 30 c.c. every four hours until there was relaxation of muscles and cessation of spasms, eight doses in all. From his experience, this treatment seems to be of the greatest value, though it is necessary to continue the injections as long as any muscular rigidity exists, the frequency of the dose depending entirely on the action of the poison. When necessary, chloroform, morphin and chloral, as needed, should be given. These two are the only successful cases out of six treated by him in sixteen years.

37. **Dual Action of the Brain.**—Inglis holds that we do all our thinking with one side of the brain, the other having an entirely subordinate part and being called into independent action only under special and pathologic conditions. He supports this theory by the usual arguments of righthandedness, double consciousness, etc., and explains by it certain facts of mental disorders observed. He believes the attempt to counteract righthandedness or produce ambidexterity is a physiologic crime.

39. **Causation of Appendicitis, Etc.**—The fecal theory of appendicitis is a thing of the past, and Byrne considers the etiology now largely a matter of malposition favoring the deposition of concretions, inflammation, local inflammations, exposure, traumatism, etc. He thinks the slight immunity in early life can be credited in the large majority of cases to the fact that the normal retrograde changes and their natural consequences in the organ have not progressed far enough to interfere with the integrity of the part until after the fifteenth year. He reports a case in which he was able to squeeze out the hard fecal matters from the appendix during life, with the best results. This procedure he thinks is a novel one and, therefore, calls attention to it.

40. **Thyroid Extract.**—Drewry and Henderson have experimented on eighty-eight cases in the Central Hospital of Virginia, including cases of mania, melancholia—acute and chronic—epilepsy, primary dementia, terminal dementia, paretic dementia, paranoia, circular insanity and imbecility of various durations in both sexes. The doses were from 2 to 60 gr. of Parke, Davis & Co.'s extract given two to six times a day and generally gradually increased. The duration of treatment was from 14 to 90 days, sometimes interrupted, some patients being kept in bed under special diet. Careful attention was given to the hygienic regulations, and observations were made as to temperature, respiration, pulse, gastric disorders, secretions, sensory and mental symptoms, weight, etc. Control cases, one of chronic mania and one of chronic melancholia, were taken for the purpose of comparison. From the results of the experiments they were unable to see that the thyroid produced any uniform, definite action on the pulse-rate, secretion, etc. There were unfavorable symptoms, such as gastric disorders, nausea, anorexia, etc., in only three or four cases, and in no case was there any dangerous symptom. One patient, who had never taken a dose before, was given 60 grains at once without any bad effects. They observed no decided mental changes, and while there was more or less effect on the weight, they do not find any unfavorable results on either the mental or physical conditions. From their experience they conclude: 1. That it is a remedy of certainly very limited value, if any, in the treatment of any form of insanity. 2. That those cases apparently benefited by it, owe their improvement or recovery as much, or perhaps more, to other agencies—such as better nursing and attention, rest, diet, tonics, etc.—than to the thyroid. 3. That it is in the so-called curable cases—acute forms—that improvement or recovery seems to be the result of thyroid treatment, cases that would either get well without any special medicinal treatment, or from the treatment usually followed in such cases. 4. That ordinary thyroid extract may be given with impunity without producing dangerous symptoms of any kind. 5. That having tried every rational line of treatment without effect, it is perhaps well to give the thyroid treatment a trial.

41. See also ¶ 11, above.

42. See editorial in this issue.

43. **Medicolegal Relations of the X-Ray.**—The following is the substance of the conclusions offered the American Surgical Association, on the medicolegal relations of the X-ray, by the chairman, Dr. J. Wm. White. The routine employment of the X-ray in cases of fracture is not of sufficient definite advantage to authorize its employment in every instance. In case of doubtful diagnosis, this, as well as other means, should be employed, but the grave possibilities of misinterpretation should not be overlooked, as there is evidence that mistakes may be made by competent operators. In the regions of the base of the skull, spine, pelvis and hip, the X-ray results have not as yet been very satisfactory, and on account of the rarity of good skiagraphs of these parts, special caution be observed when they are affected, in basing on X . any important diagnosis or line of treatment. A

of deformity, skiagraphs alone, without expert surgical interpretation, are generally useless and frequently misleading. Apparent deformity may be produced in normal bone and existing deformity greatly exaggerated. It is not possible to distinguish, after recent fractures, cases where perfectly satisfactory callus has formed from those that later go on to non-union. Fibrous union can not be distinguished from union by callus where lime salts have not been deposited. In these cases, the X-ray should be regarded as an adjunct to other surgical methods and its testimony as especially fallible. Evidence appears to show that in the majority of cases X-ray burns are easily preventable, and though the essential cause is not settled, it is possible that idiosyncrasy may make some persons especially liable to this injury. In the recognition of foreign bodies, the skiagraph is of the greatest value, though in their localization it has occasionally failed. The surgeon who bases an important operation on the localization of a foreign body should remember the possibility of error. The situation from a legal standpoint would vary in different states and with different judges, but in many places and in many differing circumstances, the skiagraph will affect medicolegal questions. The technicalities of its production and the manipulation of the apparatus are already in the hands of specialists, and it is quite necessary that the surgeon should so familiarize himself with the appearance of skiagraphs and their distortions, and with the relative value of their shadow and outline as to be the judge of their teachings and not have to depend on interpretations of others who may lack the wide experience necessary for their correct reading.

47. **Eye Symptoms in Tabes.**—Oliver divides tabes into two types, a gross optic type, in which the eye symptoms appear as visual paresthesias and contracted fields, followed later by degenerative symptoms, with apparent intermissions and improvement, but terminating in total blindness; some of the well-known pupilary and extraocular muscular signs becoming manifest in 30 to 50 per cent. of cases. In the other type the eye symptoms seldom come before the specialist, though, in a great majority of instances, they exist to a certain extent. There is an absence of growths and inflammatory signs in ocular structures and the vision finally largely disappears.

48. **Diabetes.**—Herrick calls attention to the phenomenon of casts in the urine during diabetic coma as possibly being of some value in its early diagnosis, and also of an occasionally low specific gravity of saccharine diabetic urine. The importance of this fact to the life-insurance examiner is evident, since so much depends on the specific gravity in their ordinary diagnosis of diabetes.

49. See abstract in The Journal of May 5, p. 1129.

51. **Serum Diagnosis of Tuberculosis.**—Edsall gives a critical summary of the literature of tuberculin tests, and concludes from a study of the facts that, whatever the clinical value of the method may prove to be, it deserves to be tested more widely, as its value is at present hardly definitely decided.

52. See abstract in The Journal of April 28, p. 1069.

53. Ibid., March 10, p. 623.

54. Ibid., June 2, p. 1418.

58. **The Leucocyte Count.**—The value of this count in surgery is discussed by Dunham, who points out where it is probably a safe guide, and where, under certain special conditions, perplexity may arise. The conditions in which it is increased are: digestion leucocytosis, variation from age, hemorrhage and ether operations; and on a basis of one case, absorption of iodoform probably materially increases the count. Carcinomata seem to increase the leucocyte count, as do also sarcomata; acute inflammatory conditions offer the best service to the surgeon in the diagnosis by this means. As a rule, other things being excluded, it is a safe guide to the presence of acute sepsis, but sometimes the count is not strikingly high. There may be instances where the number of leucocytes is not obvious and yet suppuration exists, but there we have a quantitative change in the iodin reaction of the polymorphonuclear neutrophiles, that is not observed in the normal blood or in disease which can be confounded with acute abscess. The question whether there is an iodin reaction where the leucocytosis fails is of interest, and if it is always present ,it will be an invaluable aid to diagnosis in these cases. He also mentions certain points in regard to the technique of blood counting and lays particular stress on the importance of the surgeon himself ascertaining its bearing on the case in hand.

61. **Thyroid Medication in Cases of Fractures.**—Murray reports a case of ununited fracture of the femur in which thyroid medication was employed with a view to influencing the nutrition. It seems to have been of benefit, as there has been great improvement since the beginning of medication, and complete consolidation of the fracture seems to be only a matter of time. While a definite conclusion can not be attempted as to this treatment, he believes that we are justified in trying this in case of non-union, before resorting to operative measures.

71.—Ibid.

77. **Genito-Urinary Tuberculosis.**—The paper by Sondern is very full in regard to the laboratory methods of diagnosis of tubercle bacillus in the urine and should be read to be appreciated, as an abstract can not be given, within reasonable length, to do it justice.

78.—This article has appeared elsewhere. See The Journal of May 12, ¶ 29, p. 1185.

79. **Parasitic Skin Diseases.**—Corlett says that next to eczema, epizoic dermatoses are the most prevalent of all skin diseases, the animal and vegetable kingdom being about equally represented. The ringworm family in this country is of greatest importance. The parasitic diseases, due to the animal parasites, are apparently somewhat decreasing, while those due to the vegetable organism seem to be slightly on the increase. The principal sources of infection are the crowding together of children in schools and asylums, the slum districts, and domestic animals. Kindergartens are a frequent source of trouble, as are also the barber shop and unclean towels. He calls attention to the parasitic troubles contracted from domestic animals, especially the ringworm from horses and calves, which is more virulent than that obtained from fowls, dogs and cats. The measures he suggested for checking these diseases are the inspection and regulation of barber shops, instruction as to the habits of cleanliness, especially in public washing places, etc., and care as to any disease appearing among animals.

80. **Sterility in the Male.**—Obstruction of the seminal channels has received the largest share of attention, and the condition of the testicle itself has been more or less neglected. Rice describes what he has found that is pathologic in this organ, and claims that deviations from the normal are extremely frequent, and that the lesions may be localized and limited to certain special tubules. He finds that there are two great classes of suspended or destroyed spermatogenesis, with and without associated changes surrounding the seminiferous tubules. In a few cases he has found it without changes, and in a large majority, only partial, some portions being normally active. This condition has been observed in individuals as young as 24 years of age, and as old as 53, and the cause is not entirely clear. In a much larger class, he finds one common lesion, the formation of a zone of hyaline tisue around the tubule in the place of the normal flat connective-tissue cells which form their physiologic sheath. These are associated with degenerative changes of the epithelium in various degrees and may be partial or total, while the rest of the apparatus may be absolutely normal. The only other changes, which were found now and then associated with epithelial destruction, were of an endarteritic nature and were not regularly observed. The condition is more frequently bilateral, but may be more pronounced on one side than the

other. There may be complete atrophy of the glands. Wherever this condition occurs, it can be recognized macroscopically, not necessarily by the size and consistency of the organ, but by the whitish, homogeneous stripes on its surface. In the treatment of sterility, surgical investigation is especially useful. In the case of obliteration of the vas deferens, surgical interference does not seem hopeless. Experimental anastomosis has been successfully practiced on the dog by Van Hook. If the vas deferens or the epididymis appears normal, it will be correct to split the testicle and examine its cut surface, and also some of the juice squeezed out. Suturing of the split testicle is neither difficult nor dangerous.

82. **Asynchronism in Mitral Stenosis.**—The object of Gibbes' paper is to discuss the mechanism of mitral stenosis, and he says that the special occurrence of presystolic murmur is due to reduplication of the first sound, in consequence of the two sides of the heart not acting synchronously. He thinks that proper recognition of the result of asynchronism is of the greatest importance in all forms of valvular disease, but essentially for the correct diagnosis of mitral stenosis.

88. See abstract in The Journal of April 28, p. 1070.

91. **Lesions of Frontal Sinus.**—Sattler describes the anatomy and development of the frontal sinus, its general diseased conditions and the changes which then occur. The symptoms are described, including edema and ptosis, exophthalmus, etc. The treatment is entirely surgical, the only method advisable being the external operation, which is described in detail.

92. **Atrophic Rhinitis.**—French, in his discussion of this condition, speaks especially of the need of asepsis and the almost impossibility of obtaining this with the ordinary syringes used. He has tested those that have been generally used and superficially cleansed, and finds them highly septic. Atomizers should also be sterilized by boiling. Oils should be used sparingly, and then only after cleansing the affected parts with saline wash; they should be preceded and succeeded by sprays of hydrogen peroxid. The antitoxic treatment of Belfanti and Della Vedova is mentioned, and he refers to a letter from Mygind, of Copenhagen, who regards this as most effective, but with so many drawbacks that he has been obliged to abandon it. The majority of patients with this disease will recover. Change of climate, tonics, iodin, arsenic and cod-liver oil will be found beneficial. The clothing should also receive attention; woolen undergarments to be but for the protection from colds, which may be an advantage.

97. **Hay-Fever.**—Abrams says that the treatment of this disease requires close attention to all details regarding the patient's habits of life, idiosyncrasy, diet, etc., for a considerable period of time. Any surgical measures required should be applied when the patient is not suffering from the disease, and some caution should be used in the employment of drugs that enthrall, as hay-fever patients are usually very sensitive to the action of such.

102. **The Ray Fungi.**—Hektoen's paper is the monograph which received the *Chicago Medical Recorder* prize for 1899 and 1900, and it is impossible to abstract it adequately here.

103. **Rapid Osteoclasis.**—Blanchard advocates rapid osteoclasis in certain cases of deformity, especially those of the femur and tibia, it being rapid and satisfactory in its results. He speaks of the Grattan osteoclast, which he thinks has been injured and has lost reputation because it has been made lighter and less massive in construction.

107.—See abstract in The Journal of May 12, p. 1194.

108.—Ibid., p. 1195.

118. **Thermotherapeutics.**—Cushing reports briefly his experience with thirty-seven cases treated with hot air. He has tried six different kinds of apparatus, none of which are entirely satisfactory. He has had some unpleasant experiences, some failures, and some accidental burns, but he has also had quite a number of striking successes. About 80 per cent. of the total number of patients were either relieved or cured. The list of disorders includes: acute, subacute, chronic and muscular rheumatism, gonorrheal rheumatism, traumatic synovitis, arthritis, tendo-synovitis, sprains, inflammation from various causes, varicose ulcers, gout, fibrous ankylosis and perichondritis. In a case of rheumatoid arthritis and one of syphilitic nodes, the treatment was a failure.

124.—This article has appeared elsewhere. See The Journal of June 23, ¶ 24, p. 1651.

126.—See abstract in The Journal of April 21, p. 1004.

127. **Sigmoid Sinus Thrombosis.**—M'Kernon describes a number of cases and analyzes the symptoms that were always present, the history, etc. Chills were noticed in a large proportion of cases, sometimes a chilly sensation only, but the cases in which no chills were observed were non-infecting in character. The temperature varied according to the amount of septic matter entering the circulation which, if large, is immediately followed by a rise from normal to 104 F., or even higher. If septic infection is slight, the rise will be gradual. Collections of pus in the brain may very materially lower the temperature and should always be thought of when this occurs. With the high elevation in temperature, there is a corresponding increase in the pulse-rate, but temperature may be subnormal when complicated with cerebral abscess. Pain is generally present and greater than that of ordinary mastoiditis, especially in the side of the head and in the occipital region over the torcular. Nausea and vomiting are nearly always present in a greater or less degree. Respiration is but little affected in the later stages. In two of his cases, the respirations reached about 60 per minute. Vertigo was not observed in his cases, though it is generally present when the meninges are involved. Consciousness was affected in all except one of the patients operated on. A slowness of cerebration was manifest. Neuroretinitis was present in two of the patients examined. Motor disturbances were absent in all. Puffiness of the eyelids of the affected side was present twice. Constipation was present in all the cases. Edema of the mastoid region and over the mastoid and occipital veins was seen in five of the seven cases operated upon. Gerhart's symptom, that of increased quantity of blood passing through the jugular of the unaffected side when pressure is exerted over both the external jugular veins, was not seen. In all his cases there was marked stiffness and, in two instances, rigidity of the muscles of the neck on the affected side. He found no hard cord-like swelling along the course of the internal jugular. In two of his jugular cases, the lymphatic glandular involvement was very marked. Among the general symptoms at the onset of the disease may be mentioned malaise, loss of appetite, a heavily furred tongue and foul breath. The face wears an anxious and pallid look, the skin is dry and later presents a yellowish tinge, indicating sepsis. It is said that sinus phlebitis is a disease of adult life, but in one of his cases it occurred in a child 3 years of age. Treatment should be individual. A complete and thorough exposure of the sinus before it is opened is desirable in all cases. The field of operation should then be flushed with hydrogen peroxid, from which he has never observed any ill effects. This should be followed with a second flushing with absolute alcohol, and a freshly sterilized aspirating needle should be thrust through the dura covering the sinus; it should be introduced for one or two inches, along the lumen of the vessel. If a negative result be obtained and the appearance leads still to doubt, it is better to make a small opening in the dura than to limit the procedure to simply an unsatisfactory aspiration. When a clot is found, the dura covering the sinus should be opened freely, the clot removed with a curette, together with any disintegrating material that may be present. When the bloodflow is established from the proximal end, it should be allowed to continue for a few seconds, so as to remove any further clot or septic material. It is then easily controlled by packing directly against the lumen of the vessel. The lower portion of the sinus should be treated in the same manner,
removal of the clot an attempt should be made to
circulation at the bulb. When the sinus has been
an aseptic clot or the presence of pus and there is

involvement, he thinks it better to cleanse the operative field and pack the sinus firmly at the bulb with gauze, than to proceed any further. If a disintegrated clot, or pus, or both are present, we should expose as rapidly as possible, ligate at the clavicle and resect and remove the jugular at that side to its commencement at the bulb. In the facial, maxillary, thyroid, or other veins be involved, they should be ligated beyond their point of involvement and resected. All enlarged glands should also be removed, to prevent possible infection. Care should be taken to completely separate the pneumogastric nerve from the vein at the lower point of ligation. The soft tissues of the neck should be flushed by hot saline solution and closed by sutures to within an inch of the bulb. After this it is easy to remove the pus and disintegrated material in the sinus. If any sloughing edges over the dura be present, they should be removed. In all cases of aural disease, especially operative cases, we should have these discharges examined microscopically and the streptococcus will generally be found in septic cases. The time to operate on cases of sinus thrombosis is immediately after the diagnosis is made. When in doubt, it is better to make an exploratory operation than to wait. During prolonged operation, he knows no better method of stimulation than a high saline enema, repeated if necessary. If the patient does not respond quickly after being put to bed and other means of stimulation are required, direct transfusion of normal salt solution can be done. One of the most valuable aids in the immediate recovery of his patients was the administration of oxygen immediately after the operation, and continuing the administration at stated intervals for three or four days thereafter. This, with a generally supporting treatment, constituted the after-care of the patients.

133.—This article has appeared elsewhere. See The Journal of July 14.

134. **Water-Supply and Disposal.**—Rodman's article is an interesting one, bearing on the questions of sanitation and water-supply and disposal. He concludes that while sand filtration may be useful in cases where there is a convenient desert, the bacterial is the coming method of sewage disposal. Equally important with the disposal of sewage is the question of filtration, and it is just as necessary that the water used for domestic purposes should be filtered as that it should be rendered harmless after using. To perfect sewage disposal and neglect water filtration is as irrational, he says, as would be the antiseptic methods of surgery did they consist solely in disinfection of cast-off dressings.

142. **Surgical Diseases of the Spanish-American War.**—Senn gives a brief general statement of some of the principal facts observed by him in Cuba and Porto Rico. One thing notable was the readiness with which the Mauser bullet wounds healed and the limited zone of contusion. Many of the individuals who suffered from flesh wounds hardly noticed them at the time. The value of the first-aid dressing and the aseptic character of the bullet were also notable. Wound infection he thought was generally due to too frequent dressings, and useless attempts at probing the wounds. Another notable point was the number of gunshot wounds of the abdomen in which the patients recovered without laparotomy. He was the first to place himself on record, basing his opinion on the results of experiments, that a man shot through the abdomen from before backward on the level with the umbilicus or above, has a fair chance of recovery without operative interference. In these cases the intestinal canal not infrequently escapes injury. These are the cases that recovered during the late war and in almost every instance the wound was on the level with or above the umbilicus, while if it was below that point, the chance of intestinal wounds was greatly increased. In penetrating wounds of the chest the same was true as regards recovery without operation, and in but few did he find even extensive pneumothorax. There were no subjective or objective symptoms indicating injury, and recovery generally followed within a few days. He believes that too early aspiration in cases of chest wounds may increase hemorrhage and this procedure is justifiable only after the accumulated blood in the pleural cavity has fulfilled its legitimate functions and served the purpose of an efficient hemostatic by effecting pulmonary compression, or after sufficient time has elapsed and there is no danger of recurrence of the internal bleeding. One part of the surgical treatment of the wound was unsatisfactory, and that was the lack of early immobilization of fractured limbs, which was partly due to want of proper materials. The most valuable available material was the cocoa-palm leaf, which was found to be most excellent. He regrets that immediate immobilization was not practiced on a larger scale. Another statement was, that, in contrast to early experience, penetrating wounds of the knee-joint, hip-joint and larger joints recovered promptly without loss of function. He does not think that more than 400 lives were lost in battle or as the result of secondary complications of gunshot injuries. The loss of life was due to typhoid and tropical diseases, such as malaria, etc. Another thing of which he is positive, so far as the Illinois troops were concerned, is that there was not a single case of hernia sent to the front, but many came back with such troubles. He thinks this is due to the reflex interference of climate and the disappearance of fat in the region of the inguinal canal. He examined 10,000 men at Camp Tanner and found varicocele very frequently—in at least 25 per cent. of the applicants. In not more than 2 per cent. did the recruit acknowledge that he experienced any inconvenience whatever, and he now believes, judging from observation of men who returned, that it is not a serious disqualification for military service. Patients who required treatment of this condition after active service suffered from the same causes as those which produce hernia.

149. **Smallpox and Yaws.**—Meek believes that the epidemic of supposed smallpox that occurred in his section of Texas was entirely one of yaws. He treated the cases as such and all his patients recovered.

153. **Is Alcohol a Food?**—Gasser has studied the food value of alcohol and concludes that in moderate quantities it is a form of food, but when used in excess, a poison. While, when used in moderation, it is not specially injurious, still there is no practice which is more seductive and alluring in the formation of a bad habit, and while it may afford some pleasure and gratification it is not necessary. A safer, more free and happier life can be obtained by total abstinence. He does not speak favorably of even a moderate use of alcohol for its possible food value.

FOREIGN.

Dublin Medical Journal, July.

On Symptoms or Phenomena Formerly Known as Croup; the Diseases Which Produce Them; and the Clinical Significance of the Various Allied Affections Embraced by the Term. Langford Symes.—The writer, from an analysis of the different forms of disease which have passed under the name of "croup," concludes that there is no such true disease as croup and that the symptoms are most likely to be due to diphtheria or laryngitis stridulosa. In difficult and doubtful cases we should suspect diphtheria and treat it as such from the start with antitoxin. Recession and restlessness are the two most dangerous symptoms. Since antitoxin reduces the mortality in diphtheria and helps the cases to be tided over the crisis by intubation, it may possibly contribute to the future success of tracheotomy. Deaths registered as croup are mainly due to diphtheria.

British Medical Journal, June 30.

The Application of Pathology to Surgery. HENRY T. BUTLIN.—The author first shows how little surgery owed to pathology in the remote past; in fact, pathology can hardly be said to have existed at all until the time of Morgagni and Hunter, for the latter's operation for aneurysm was the first instance, up to date, of attempted surgical invention founded on pathology by the inventor. The second was of recent times, the Lister antisepsis. At present, the value of pathology to surgery is no longer questioned. The applications of pathology which have been made during the last fifteen years have been so increased and so important that we are coming to have an implicit trust in pathologic foundation. We may be disappointed in our expectations in many instances, and he reviews the means that are at our disposal and discusses the possibility of other improvements. The fact that researches appear to have no direct bearing is not a reason for their rejection, and he quotes in this connection the discoveries of Faraday on electricity and magnetism which seemed at the time purely scientific and yet their direct practical applications at the present time are multitudinous. He believes that many inventions can be made to order, so that when needed, the resource will be at hand. We should require two kinds of pathologic laboratories, one for purely scientific research without reference to its application, and the other for research in applied pathology. He points out that the combination of both of these is practiced in the great industrial establishments of Germany, especially those connected with color industries, where workers are employed at great cost, and original research of every kind, whether of direct importance or not, is encouraged by commercial men who recognize the fact that everything may possess a value.

Degeneration of the Neurone. FREDERICK W. MOTT.—In this lecture Mott describes the effects of injury of the neurone showing that besides the direct Wallerian degeneration there is an effect from want of stimulus upon the nerve-cell itself. He does not believe that the recent studies of Marinesco and Von Gudden are especially contradictory to, or that they annul the validity of, the Wallerian doctrine, and holds that there is no evidence to show that degeneration occurs except in the peripheral portions of the nerves and in the central portion up to the next node of Ranvier unless the injury is so great as to cause such a shock to the neurone that it dies as a whole. In considering the causes of degeneration of the neurone, it is necessary to point out the results of: 1, failure of blood-supply; 2, toxic conditions of the blood; 3, the effect of excess or deficiency of stimulation; 4, inherited defects in the nervous system as a whole or in special parts of it. The effects of anemia have been subject to numerous experiments and he describes the lesions found by Hill after ligation of both the carotids and the vertebral arteries. These cause cell-degeneration and finally destruction, producing also paretic and demented conditions in the animal. This subject has a direct importance, as ligation of the carotid for aneurysm has produced hemiplegia and he has been able to tell by microscopic examinations of specimens of the cortex without a clinical history which side of the body was paralyzed. In experimental anemia of the spinal cord caused by clamping the abdominal arteries, the exogenus fibers of the posterior columns and the pyramidal tracts which have their trophic centers in the cortex do not undergo degeneration like those having their centers in the gray matter of the cord itself. He shows the effects of experimental anemia on the cord and that very slight pressure upon the vessels may produce decided functional symptoms. Hemorrhage of itself may be extensive without causing appreciable changes in the nervous elements. Inanition, even when extreme, causes little or no loss of weight of the nervous system or change of the nerve elements. In wasting diseases affecting the nervous organs the trouble can hardly be due to anything but to their failure to assimilate from the blood the necessary material for their vital energy. They die in reverse order of their evolution: first, the peripheral parts, and last, the trophic and genetic centers themselves. Hyperpyrexia is also mentioned, its effects on the nervous elements considered and the changes found by the Nissl method described. A temperature of 109.5 F. causes coagulation and death of protoplasm and affects first and most markedly the periphery of the cell while the prolonged high temperature of 107 to 108 F. will also do the same. Still it is shown that a certain degree of this coagulation may take place with recovery, and he explains thus the remission of symptoms following the application of cold baths, etc., in certain cases of fever. While he thinks these facts support Osler's view that some of the extreme cases of so-called hysterical hyperpyrexia are fraudulent, yet there are some cases that are impossible to explain, showing that a temperature of even 114 F. for a short time may be compatible with life. The latter part of the lecture is taken up with the effects of toxic conditions of the blood and the selective action of certain poisons on the nervous system.

Lead Encephalopathy and the Use of Diachylon as an Abortifacient. W. B. RANSOM.—The writer reports three cases of cerebral disease due to lead poisoning, two of which were caused by diachylon taken to produce abortion. In these cases there was optic neuritis, headache, in one case ataxia, in another a certain degree of paresis, and epileptic attacks were observed in one instance. Other cases are reported in which lead taken for the same purpose produced the other symptoms of lead poisoning to a marked degree and he thinks that its use for this purpose is becoming a dangerous and widespread practice in England. He says that penny balls of emplastrum plumbi are kept at the druggists and that no restriction is put upon its sale. It appears to be an uncertain abortifacient, always injurious, and is often fatal or leaves permanent bodily or mental enfeeblement.

The Lancet, June 30.

The Primary Disorders of Growth. HASTINGS GIFFORD.—The writer discusses the various growths of hypoplasia, hypertrophy, degenerative hypoplasia and degenerative hyperplasia all represented in the skeletal growth. In the one group hypoplasia and hypertrophy are distinguished by mere defect or excess of normal growth; while in the other all the broad clinical and anatomical features characteristic of degenerative diseases of growth, whatever the tissue may be that they affect, are present. The degenerative hypoplasia of the skeleton is seen to run into degenerative hyperplasia by imperceptible gradations, each being distinguished by characteristics imprinted by age alone. The degenerative hyperplasia is divided into two diseases, according to the tissue; if it affects the hard substance of the skeleton especially it is called "osteitis deformans," if the soft substance is involved it is called "osteomalacia." As a rule these two diseases are well defined, though in all cases both the clinical and material characteristics in the one can be traced in the other. The differences between these are in the main due to tissue, function, sex and age alone. They are due to variations of the part affected and not of the function itself. What has been said of the skeleton and its growth diseases is also true in effect of all other tissues and their growth disorders. All are liable to the same four kinds of disorders and affected in the same way, varying only to the extent that one tissue differs from another, one time of life from another, one function from another and one sex from another.

Use of Mercury in the Treatment of Cardiac Failure Due to Arteriosclerosis. ALEXANDER MORISON.—The case reported is that of a man about 67 years of age, with good habits, who suffered from cardiac arrhythmia, anasarca, very rapid and irregular pulse, and some foul sores on the leg. He was treated with various remedies, but was finally put under the *pilula diuretica* of the hospital pharmacopeia, to be administered three times a day, which consisted of digitalis, squills, blue pill and extract of hyoscyanus, each 1 gr. The improvement was rather rapid, and he was soon put in a comfortable condition. The kidneys in this case were especially healthy, which is an important fact in connection with the use of mercury. The author calls especial attention to the value of mercury in this form of trouble. He thinks [illegible] considerable share of its importance is due to its [illegible] the pulse tension. He [illegible] the [illegible] peripheral vessels by a [illegible] their [illegible] ically demonstrable fact, and it is possible to suppose that the combination of mercury (a peripheral dilatant) with digitalis and squills, which are in part central stimulants as well as peripheral contractors, makes it a rational adjuvant to the action of the latter in cardiac failure due to arteriosclerosis.

Brazil Medico (Rio Janeiro), June 1.

Food Value of Tasajo. MERCANTI.—The Institute of Hygiene at Buenos Aires announces that the dried and salted beef prepared in South America under the name of "tasajo," or "xarque," contains at least twice as much albuminoid substances as the same weight of fresh meat, while it can be sold in foreign markets for one-half or one-third of the price.

Bulletin de l' Academie de Medicine (Paris), June 19.

Disinfection of Wells with Permanganate. E. DELORME.—The wells used by the regiments during their triennial encampment at Châlons became unfit for use during the interval, and Delorme thoroughly cleansed and disinfected them, using the system of oxidizing disinfection proposed by Mme. Schipiloff, which costs less than twenty cents a well. He measured the depth of the water with a string and weight, and knowing the diameter, calculated the amount of disinfectant required to form 1 per cent. of the cubic contents. The disinfectant used was potassium permanganate, although he observes that calcium permanganate would answer the same purpose. The water was then thoroughly stirred, and at the end of half an hour, when a sample showed the dregs-of-wine stain, a small amount of powdered charcoal and fine sand, sterilized in the oven, was shaken into the well. The water was clear and sterile in three or four days, when the well was entirely emptied. The fresh water that accumulated contained no pathogenic bacteria and the number of microbes of all kinds had been reduced from more than 72,000 to 1,026 per c.c., in one well, which was about the average.

Journal de Medecine (Paris) June 24.

Artificial Fecundation. A. LUTAUD.—In concluding a study of the various causes of sterility and the treatment of this condition, Lutaud recommends artificial fecundation as a practical and harmless means of remedying certain varieties of sterility as a last resort, which he hopes will soon take the place it deserves in gynecologic practice. Investigation of the husband's spermatozoa should precede treatment of sterility in all cases. After a normal coitus the wife remains quietly in bed until the arrival of the physician—Lutaud was successful in one instance in which there had been an interval of four hours. He then inserts a Ferguson speculum into the vagina, which collects the semen in the vicinity of the cervix. A small amount is aspirated with a Sims glass canula and a single drop of the fluid is injected into the cavity of the uterus. If the menses recur as usual, it is evidence that there has been no fecundation and the operation is repeated during the following week. If there is no conception after four or five successive attempts, it is useless to continue.

Presse Medicale (Paris) June 13.

Raw Meat in Tuberculosis. A. SICARD.—The effect of "zomotherapy"—as Richet calls his experiments with 328 dogs inoculated with tuberculosis and then fed on raw meat—indicates that the raw muscle juice has a specific, antitoxic power in regard to the tubercle bacillus. The dogs survived on an average 300 days, and some for two and a half years, while the control animals all readily succumbed. Sicard discusses the various theories advanced to explain these facts, and suggests that it would be interesting to determine whether other food elements, cod-liver oil for instance, administered to dogs and guinea-pigs in sufficient amounts, would have an inhibiting action on the evolution of experimental bacillosis; also whether forced ingestion of raw or dried meat would transform the cellular or humoral medium in animals and render them refractory to infection.

JUNE 16.

Treatment of Fibromyomata of the Uterus. S. DUPLAY.—The writer counsels operating, especially on young women, even in the absence of functional disturbances, when the fibroma is constantly increasing in size, and without waiting for it to attain excessive proportions. Functional disturbances indicate intervention, unless they can be kept under control by therapeutic measures, but phenomena indicating compression or sepsis and torsion of the pedicle demand immediate intervention. He removes the uterus and appendages by laparotomy, not leaving even a pedicle, but drains through the vagina.

Superalimentation in the Treatment of Tuberculosis. M. LETULLE.—Careful comparative study of 380 tuberculous patients at the Boucicaut hospital during the last two and a half years has shown that the cure d' aliments at the hospital—everything combined to tempt the appetite of the patients with nourishing food—is easily accomplished, is inexpensive and has frequently a most favorable effect at any stage of the disease. Men and the younger patients derive the greatest benefit. The increase in weight is most pronounced during the first four to six weeks. When weight becomes stationary, the patient should be sent to the country, as the hospital has accomplished all that can be expected of it.

Surgical Treatment of Paresthetic Meralgia. A. CHIPAULT.—In three cases of severe, absolutely rebellious meralgia Chipault obtained a complete cure by resection of 3 to 4 cm. of the femoro-cutaneous nerve at the innominate notch. In each case transient improvement was followed by recurrence of the pain after the operation, which gradually subsided, and the cure was complete at the end of the second month. A peculiar feature in each case was the localization of the pains in the territory innervated by the resected nerve, during the exacerbation after the operation.

JUNE 20.

Raw Meat in Tuberculosis. O. MARTIN.—During the last four months the writer has been administering pulverized desiccated raw meat to his tuberculous patients, and announces that all in the early stages of the disease have been cured by it. The general health and weight improved, the strength returned, the cough vanished and the lesions in the lungs became cicatrized. This improvement has persisted since the meat has been abandoned. The dose was two to four tablespoonfuls, administered for two and a half months, at least. He is convinced that raw meat has the specific, antitoxic power attributed to it by Richet, as mentioned above.

When to Operate in Acute Otitis. M. LERMOYEZ.—The patient's account is seldom reliable. The skin over the mastoid is also deceptive. Trephining is a necessity in every case of fistula, whether opening into the ear or outside, and also in case of periosteal abscess. Pain on pressure over the point of the mastoid is constant in every acute otitis; at the base of the mastoid it suggests mastoiditis; at the posterior margin of the mastoid it is still more disquieting, and should banish the last hesitation on the part of the surgeon. Torticollis indicates a mastoid abscess burrowing deep in the neck, except in case of lymphatic children with tumefaction of the substernomastoid ganglia accompanying or consecutive to an acute, possibly slight otitis. The adenopathy persists and may induce torticollis, although the mastoid is sound. In case of tumefaction of the soft parts over the mastoid, with edema, examine it every day, and if a point of fluctuation is discovered in the midst of the edema, operate at once. A still more important indication is furnished by the swelling of the mastoid en masse, with the skin normal, scarcely to be distinguished except by comparing the two sides, always bearing in mind that the right is normally the larger. Trephine then immediately, as there is every chance that the internal sinus is already bathed in pus. If abundant suppuration persists after a month of rational treatment, and the amount increases, mastoid otitis is certain. If the discharge remains fetid, it indicates some old lesion, generally a cholesteatoma. In this case trephining is insufficient and total petromastoid evacuation is demanded. Otogenic fever, no matter how high, indicates merely paracentesis, if the tympanum has not been sufficiently opened, but if the tympanum is amply incised, otogenic fever of even 38 C., demands trephining. With cerebral symptoms, first investigate whether they are exclusively otogenic, and in this case, merely incise the tympanum; if they persist, trephine the mastoid the next day, but do not go beyond the antrum. If this does not afford relief, open the skull the following day, but always proceed by one step a day. If the ophthalmoscope shows the eye intact, the chances are in favor of "simple meningism;" hyperemia of the papilla warns of approaching cerebral complication, and optic neuritis indicates a developed meningo-encephalitic lesion. Mastoid lesions are more precocious and profound in the otitis due to scarlet fever or la grippe than in that which follows measles or a cold. Hemophilia, advanced diabetes and cachexia, but not meningitis, are contraindications to operation. Instances have been recorded of otitic meningitis cured by extensive trephining of the mastoid without opening the dura. In all doubtful cases of acute otitis, operate, but never make Wilde's incision. It can never do good and may do much harm. It has never cured except in case of mere retroauricular adenophlegmons, and owes its reputation exclusively to errors in diagnosis. Further data for differentiation of an acute mastoiditis consecutive to otitis media are that the spontaneous pain is not affected by mastication; that pain is induced by perpendicular pressure of the surface of the bone: that traction of the auricle does not cause pain; that any swelling of the auditory meatus is situated in the bony part and the tumefaction is lateral, postero-superior, with a single, flat prominence; that the tympanum bulges, and is usually perforated; that muco-pus escapes after irrigation; that the hearing is much impaired, and that periauricular tumefaction does not appear until the second or third week.

Progres Medical (Paris), June 16.

Tubular Saw to Open Cavities of Ear and Face. S. DE MENDOZA.—Operations on the middle ear, the nasal fossæ and sinuses of the face are much facilitated by combining the use of gouge, drill aud a "tubular saw," the latter driven by a motor. Mendoza has adapted Stacke's protector to the tubular saw, and with this "protector trephine," as he calls it, operates with exceptional ease, rapidity, precision and freedom from danger.

Persistence of the Thymus. BOURNEVILLE AND KATZ.—The tabulated statistics given in this communication establish that the thymus persists in 100 per cent. of mentally normal children, while it is found in only 27 per cent. of idiots, epileptics and imbeciles. Examinations of the cadavers of 61 children who had died of various diseases at a general hospital, showed a persisting thymus in every case, ranging in weight from 4 gm. between the age of 1 to 6 months, to 6 gm. between the sixth month and third year, and 8 gm. in children above this age to 13 years. The thymus was exceptionally large and red in all the diphtheria cases, weighing 18 gm. in one three-year-old. In Bourneville's research at Bicêtre, on the other hand, the thymus was found in only 78 out of 298 cadavers of mentally deficient children and adults. When found, the weight ranged from 5 to 30 gm., and the age of the subjects varied from 13 months to 18 years and over.

Revue de Chirurgie (Paris), June 16.

Fibrous. Intermittent Polypus of the Rectum. M PERAIRE.—The polypus in the case reported was of the size and shape of an enormous tomato, and hung from the rectal wall by a long stem. It was hard and fibrous and had intermittently protruded during defecation and been easily replaced until it had become too large for reduction. The patient was a woman 38 years of age, and the tumor had been noticed twelve months before, a pregnancy having occurred in the interval. Cases are on record in which such polypi have dropped off spontaneously, but they usually require surgical intervention. The traction of the tumor may induce prolapse, especially in children, and recurrent slight hemorrhages may affect the general health. Fibromyomata occur in the rectum as well as in the uterus and are sometimes mistaken for abdominal tumors. Peraire cites an observation of Senn's in which laparotomy was successfully performed to remove a neoplasm supposed to be in the ovary, but found finally in the rectum, near the retrovesical cul-de-sac. Westermark removed a polypus from the anterior wall of the rectum by anterior celiotomy, but the patient succumbed to infectious accidents. In another case, the tumor extended toward the sacrum and was successfuly extirpated by Kraske's method.

Chronic Proliferating Osteomyelitis of the Bones. B. KOZLOVSKY.—It has been well established that the staphylococcus is the causative agent in chronic, as well as in acute, osteomyelitis. Kocher attributes the variability of its action to the difference in the soil of individual cases. If the soil is not favorable and the germs not very virulent, the affection is mild, suggesting the diagnosis of rheumatism. Very intense action of the staphylococci induces necrosis of the tissues and the formation of granulating foci, with vascular, sclerogenic inflammation in the bone and periosteum, manifesting itself clinically and also histologically as a periosteal or myelogenic sarcoma. Bacteriologic tests alone will determine its true nature. Six observations are related in detail, three personal. One yielded to mercurial treatment, although the patient had no acknowledged syphilitic antecedents. The rest were curetted and drained, with slow recovery. The femur was the site of the lesion in all but one case.

Compression of Kidney by Gall-bladder. E. REYMOND.—Symptoms developed suddenly in a young woman with no antecedents of biliary lithiasis or nephroptosis, which suggested stones in the gall-bladder and also renal distension. A tumor palpated below the false ribs seemed to be a distended gall-bladder, although there was no icterus, but renal colic and oliguria indicated distension of the kidney. A lumbar incision disclosed that the apparently single tumor was composed of the adherent gall-bladder and a movable kidney, both distended, the former compressing the pedicle of the latter. After nephropexy, the renal colic and oliguria vanished at once, but the temperature persisted. Seven days later, the gall-bladder was incised and several calculi removed. The organ was fastened to the skin, and the wound left open for three weeks. Recovery was prompt and complete. If the gall-bladder had been operated on first, the renal lesion might have escaped notice, and it is possible that this coincidence of lesions is more common than is generally suspected. The hydronephrosis had evidently been caused by compression of the pedicle of the kidney, as it was found very dark-colored and as the distension subsided very gradually. Several observations have been published in which gall-bladders impacted with stones have been mistaken for a movable kidney and been treated with supporting bands.

Union Medicale du Canada (Montreal), June.

Congenital Elephantiasis. J. E. DUBÉ.—Delivery of the seventh child of healthy parents in the case reported required repeated efforts with forceps for thirty minutes, and the right leg of the female infant was found much enlarged. It continued to grow in size, until at two and a half months the circumference of the leg from hip to ankle was much larger than that of the trunk at any point. The child is otherwise normal and well developed. Scarifications and compression have slightly improved the condition. About 100 gm. of a limpid, orange-yellow, viscous fluid, which coagulates at once, exudes after each scarification.

Edema of the Lung. J. A. LESAGE.—The prognosis of this serious complication of nephritis frequently depends on the method of treatment. Narcotics are dangerous and should be rigorously avoided. Venesection is indicated at once, withdrawing 300 to 500 gm. of blood, followed by dry cupping on the back and chest; mustard applications to the legs, and subcutaneous injections of large doses of ether, caffein or camphorated oil. A drastic purge is also urgently indicated, and a strict milk diet should be enforced. Alkaline lemonade, or lactose waters, are frequently found beneficial. One very obese patient was cured with a teaspoonful of tincture of ipecac every ten minutes. Another, with a valvular affection, recovered after copious venesection and digitalin.

Grece Medical (Syra) May.

Primary Sclerosis of Bladder. H. DELAGRAMMATICA.—The symptoms of "prostatism" may be simulated by primary sclerosis of the bladder with a normal prostate. It is important to differentiate these two morbid entities; the rigorous measures required in case of enlarged prostate are superfluous when the lesion is restricted to the bladder, as in the observation reported, which had been diagnosed and treated erroneously.

Hysteric Hyperthermia. LAMBIKIS.—An interesting observation of hysteric hyperthermia is r[illegible]ded [illegible] patient, a young, neurasthenic woman, complaining only of unbearable headache. The pulse was 140; respiration 28, and temperature in the axilla 44 C., or possibly still higher, as the thermometers did not record above this figure. Baths restored the temperature to normal.

Differentiation of Hemoglobinuria. B. M. Mousseos.—During the early stages of hemoglobinuria if there is cyanosis under the nails, and in the face, lips, nose and ears, the trouble is due to ingestion of quinin in 80 per cent. of the cases. This passive congestion may also appear with malarial hemoglobinuria, but it is transient and vanishes with the chill, while in quinin hemoglobinuria it lasts for several hours after the chill, and always appears two to four hours after ingestion of the quinin. The first manifestations are chill, sensation of weight in the lumbar region, slight malaise, fainting and dizzy spells. The urine is black and abundant from the commencement of the chill. These symptoms gradually subside and the urine becomes clear in eighteen to twenty-four hours, the patient feeling as well as usual. In hemoglobinuric malarial fever, on the other hand, the general symptoms increase in intensity or remain stationary; the urine returns gradually to its normal color, but a new attack occurs in twenty-four hours, with aggravation of the general symptoms and dark urine. Mousseos' practice is to administer methylene blue internally in a doubtful case, and continue it for twenty days if there is no recurrence of the hemoglobinuria after the first attack. If the general symptoms continue and the urine becomes dark-colored again, with a chill, injections of quinin are indicated. On the other hand, if the attack is repeated without recurrence of hemoglobinuria the fever is evidently pernicious, beyond the control of methylene blue taken by the mouth, and it must be administered hypodermically. By this use of methylene blue he confirms his diagnosis without losing any valuable time in attacking the malarial parasite.

Mineral Springs at the Temple of Esculapius. A. C. Dambergis.—The recently discovered site of the famous temple of Esculapius at Epidauris contains three alkaline mineral springs, similar to the waters now in vogue for gastric and gravel disturbances, and biliary lithiasis. The strongest spring is located inside the temple. The analysis is given in detail of each spring, showing .665, .558 and .628 mineral elements per thousand, mostly calcium, magnesium and sodium bicarbonates and chlorids.

Centralbatt f. Chirurgie (Leipsic), June 30.

Modification of the Murphy Button. H. Hildebrand.—In order to prevent the button from dropping into the stomach after a gastroenterostomy, Hildebrand makes the gastric half of the button much smaller and lighter than the other portion. The fibrous ring which usually forms around the opening in the stomach holds the gastric portion of the button and has a tendency to force it out into the intestine on account of its rounded top, while the opening is too small to allow the entrance of the larger portion. Kümmel has been using this modified button with satisfactory results. In one case the senile tissues did not form a constricting ring, but relaxed, leaving an orifice so large that the entire button could have been easily expelled if it had fallen into the stomach.

Deutsche Medicinische Wochenschrift (Leipsig), June 28.

Milk Bacteria in the Milk-Thermophore. Dunbar and Dreyer.—The principle of the thermophore is the gradual, prolonged generation of heat by chemical action, and it has been recommended by Frickenhaus and others to keep milk warm at night. Their statements have been comparatively disregarded, as it seemed more than probable that milk kept at the body temperature for several hours would rapidly deteriorate. The Institute of Hygiene at Hamburg has made a careful study of the subject and now announces that there is no increase in the number of microbes in milk kept for ten hours in a previously warmed thermophore. On the contrary, there is a decided decrease in the number, in both raw and Pasteurized milk—especially the latter—until no cultures can be derived from any of the germs. There is consequently no danger of deterioration of the milk in less than ten hours, and the milk-thermophore can therefore be accepted as a valuable acquisition to the technique of artificial infant-feeding.

[The director of the Institute at Hamburg, Dr. Dunbar, is a young American, from St. Paul, Minn.—Ed.]

Transmission of Tuberculosis in Milk. Lydia Rabinowitsch.—In this communication the writer confirms her previous announcements that the milk of cows with latent tuberculosis—with no clinical manifestations and only indicated by the tuberculin test—is liable to contain tubercle bacilli. Tests of milk from eight large dairies showed that those in which the tuberculin test was made systematically on all the animals had no tubercle bacilli in the milk, while they were occasionally to be found in the milk from other dairies in which the cows were tested with tuberculin only when attention was called to them by some clinical manifestation.

Fat-Embolism. H. Ribbert.—The fat-embolism that has been noted after fractures and forcible reduction of ankylosis is due to the jar of the skeleton and not to the local intervention. Any trauma associated with a jarring of the bones is liable to induce fat-embolism. It occurs when an individual jumps from a moderate height and lands with a jar, but in this case it is slight and transient. Fat is found in the lungs of rabbits dropped from the height of a table, or swung against the wall while being held by the ears, but the fat-embolism is less pronounced than in man, as rabbit bone-marrow is not so rich in fat as that of human beings. The fracture, in respect to fat-embolism, is merely an indication that the skeleton has experienced a concussion.

Muenchener Medicinische Wochenschrift, June 26.

Multiple Neuritis. C. Henrici.—Five cases of multiple neuritis were observed by the writer during the last year, illustrating the fact that this affection can be induced by quite different causes: in one by an organic poison—alcohol; in others by an inorganic—arsenic—and in the rest by an infectious disease. The pain was most intense in the alcohol cases, which were also distinguished by cerebral disturbances, two exhibiting the Korsakoff symptom-complex, i. e., rapid forgetting of recent impressions while the memory is surprisingly reliable for remote happenings. It is accompanied by pseudoreminiscences, a kind of deceptive action of the memory or pseudohallucinations. Gudden states that the tangential fibers have disappeared, and that the delirium is the manifestation of the acute cerebral lesion induced by alcohol, and the Korsakoff syndrome of the chronic lesion. In one of the women memory of the occurrences of the last few hours was defective and in the other of the last few weeks. The arsenic case was accompanied by symptoms of ataxia, a pseudoataxia which occurs in other forms of multiple neuritis. The disturbances in the gait of the patient consecutive to an infectious disease resembled those in the arsenic patient after six months of improvement.

Diphtheria Bacilli in Dejecta. J. Schoedel.—The discovery of the diphtheria bacilli in the stomach and intestines and also in the feces, in two cases, suggests the danger of infection from the dejecta.

Improved Medium for Diphtheria Bacillus. J. Schoedel.—Joos recommended a new culture-medium for the diphtheria bacillus, an alkaline mixture of blood-serum, bouillon and agar, in a communication to the *Centralblatt für Bakteriologie*, 1899, xxv, 8 to 10. Schoedel has been testing it extensively and announces that it is a great improvement over other media, as it is transparent, always ready for use and thoroughly reliable. A stab culture will retain its vitality for six months without reinoculation.

Wiener Klinische Wochenschrift, June 21.

Sign of Incipient Arteriosclerosis. F. Friedmann.—When the descending aorta is auscultated from the rear, the sound is heard most distinctly at a point which becomes constantly lower with increasing age. In case of senile involution and of arteriosclerosis at any stage, the sound is most pronounced at a point on a line between the lower corner of the scapula and the second thoracic vertebra. The second aortic sound is most distinct. A groaning sound at the angle of the scapula can, therefore, he believes, be accepted as a direct initial symptom of an arterial affection, constant even in the incipient stages.

Queries and Minor Notes.

MEDICAL PRACTICE LAW OF OHIO.

Oakland, Ill., June 25, 1900.

To the Editor.—Kindly tell me what are the medical practice laws of the State of Ohio, and greatly oblige, A. J. M.

Answer:—Since the first of July an examination is required of all persons desiring to practice medicine in the State of Ohio, with the exception of students already matriculated in Ohio medical schools.

JOURNAL ON ELECTRO-THERAPEUTICS.

Meadvville, Mo., July 3, 1900.

To the Editor.—Can you recommend a good journal on electro-therapeutics? If so, I wish you would. H. C. Johnson.

Answer:—We know of no good journal devoted especially to electro-therapeutics.

The Public Service.

Army Changes.

Movements of Army Medical Officers under orders from the Adjutant-General's Office, Washington, D. C., June 29 to July 5, 1900, inclusive:

Raoul A. Amador, acting asst.-surgeon, from New York City to Havana, Cuba, for assignment.

Harold D. Corbusier, acting asst.-surgeon, from Elmira, N. Y., to Manila, P. I., for duty in the Division of Philippines.

John S. Fogg, acting asst.-surgeon, leave of absence extended.

Robert J. Gibson, major and surgeon, U. S. A., leave of absence granted.

Edwin P. Hayward, acting asst.-surgeon, from Nebraska City, Neb., to duty in the Department of California.

Fred T. Koyle, acting asst.-surgeon, from Wellsville, N. Y., to the Division of the Philippines.

Charles H. Latimer, acting asst.-surgeon, from Washington, D. C., to the Division of the Philippines.

Robert S. Linn, acting asst.-surgeon, from Detroit, Mich., to the Division of the Philippines.

Clarence Martin, acting asst.-surgeon, from St. Louis, Mo., to the Division of the Philippines.

Omar W. Pinkston, acting asst.-surgeon, from Kansas City, Mo., to the Division of the Philippines.

Robert E. Sievers, acting asst.-surgeon, from Louisville, Ky., to the Division of the Philippines.

William Stephenson, major and surgeon, U. S. A., to proceed by transport via San Francisco, Cal., and Manila, P. I., to Taku, China, reporting in person to Brig.-Gen. Adna R. Chaffee, U. S. V., commanding the U. S. forces at or near that place.

Navy Changes.

Changes in the Medical Corps, U. S. Navy, for week ended July 7, 1900:

Surgeon O. D. Norton, detached from the *Monadnock* and ordered to duty with marines at Taku, China.

Medical Director G. W. Woods, will be detached from naval hospital, New York, and placed on retired list, Aug. 24, 1900, having reached the age of 62 years.

P. A. Surgeon F. C. Cook, detached from the naval hospital, Norfolk, Va., and ordered to naval hospital, Washington, D. C.

P. A. Surgeon J. F. Leys, detached from the *Franklin* and ordered home to wait orders.

Marine-Hospital Changes.

List of changes of station and duties of commissioned and non-commissioned officers of the U. S. Marine-Hospital Service for the seven days ending July 5, 1900:

Surgeon G. W. Stoner, detailed as temporary medical purveyor during absence on leave of medical purveyor.

Surgeon H. R. Carter, upon being relieved from duty at Havana, Cuba, directed to report at Washington, D. C., for orders.

Surgeon P. M. Carrington, granted leave of absence on account of sickness for 15 days from July 5.

Surgeon G. M. Magruder, bureau order of June 15, directing Surgeon Magruder to proceed to Memphis, Tenn., and assume command of the service, revoked, and directed to proceed to New Orleans, La., and assume command of the service.

P. A. Surgeon H. D. Geddings, detailed as acting director of hygienic laboratory during absence of the director.

P. A. Surgeon A. C. Smith, directed to proceed to New York City (Stapleton) and report to medical officer in command for duty and assignment to quarters. Granted extension of leave of absence for 8 days.

P. A. Surgeon M. J. Rosenau, upon completion of detail at International Congress of Medicine, Paris, France, to visit the Pasteur Institute and other laboratories for special temporary duty.

P. A. Surgeon C. H. Gardner, granted leave of absence for 21 days from July 19.

P. A. Surgeon Rupert Blue, granted leave of absence for 15 days.

Asst.-Surgeon H. S. Mathewson, directed to proceed to Boston, Mass., and report to medical officer in command for duty and assignment to quarters.

Asst.-Surgeon W. C. Hobdy, directed to proceed to Honolulu, H. I., and report to Surgeon D. A. Carmichael for duty.

Asst.-Surgeon F. J. Thornbury, relieved from duty at San Francisco, Cal., and directed to proceed to Port Townsend, Wash., for temporary duty.

Acting Asst.-Surgeon E. B. Hallett, granted leave of absence for two days from July 5.

Hospital Steward and Chemist W. F. Macdowell, relieved from duty at New York City, and directed to proceed to Havana, Cuba, and report to chief quarantine officer of Cuba for duty as hospital steward and chemist, and special disbursing officer.

Hospital Steward W. W. Kolb, relieved from duty at Norfolk, Va., and directed to proceed to Savannah quarantine and report to the acting asst.-surgeon in charge for duty and assignment to quarters.

Hospital Steward E. B. Scott, upon being relieved from duty at Savannah quarantine, directed to proceed to Washington, D. C., and report at the bureau for duty.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, U. S. Marine-Hospital Service, during the week ended July 7, 1900:

SMALLPOX—UNITED STATES

District of Columbia: Washington, June 23-30, 4 cases.

Illinois: Chicago, June 23-30, 2 cases.

Indiana: Evansville, June 23-30, 2 cases; Indianapolis, June 23-30, 1 case; Michigan City, June 24 to July 1, 1 case.

Kansas: Wichita, June 23-30, 6 cases.

Kentucky: Covington, June 23-30, 16 cases.

Louisiana: New Orleans, June 23-30, 12 cases, 3 deaths.

Maryland: Baltimore, June 23-30, 3 cases; Cumberland, June 16-23, 3 cases.

Massachusetts: Fall River, June 23-30, 3 cases.

Ohio: Cincinnati, June 19-26, 10 cases; Cleveland, June 23-30, 10 cases; Portsmouth, June 23-30, 1 case; Youngstown, June 23-30, 2 cases.

Pennsylvania: Pittsburg, June 23-30, 3 cases.

SMALLPOX—FOREIGN.

Austria: Prague, June 8-16, 8 cases.

China: Hongkong, May 19 to June 2, 1 case.

Egypt: Cairo, May 20 to June 3, 10 deaths.

England: Liverpool, June 8-16, 2 cases; London, June 8-16, 15 cases; Manchester, June 8-16, 1 case.

France: Lyons, June 2-16, 7 deaths; St. Eteinne, June 1-5, 3 cases.

Germany: Frankfort-on-the-Main, June 8-16, 1 death.

Greece: Athens, June 8-16, 2 cases.

India: Bombay, May 28 to June 5, 13 deaths; Calcutta, April 28 to May 5, 40 deaths; Karachi, May 28 to June 3, 12 cases, 7 deaths.

Japan: Nagasaki, June 1-10, 1 case; Osaka and Hiogo, June 2-9, 1 case.

Mexico: Chihuahua, June 8-16, 1 death; Mexico, April 30 to June 17, 164 cases, 100 deaths; Vera Cruz, June 17-23, 7 deaths.

Russia: Moscow, June 2-9, 6 cases, 5 deaths; Odessa, June 8-16, 5 cases; St. Petersburg, June 2-16, 71 cases, 18 deaths; Warsaw, June 2-9, 3 deaths.

Scotland: Glasgow, June 15-22, 66 cases.

Spain: Madrid, May 19 to June 2, 26 deaths.

Straits Settlements: Singapore, May 12-19, 1 death.

Uruguay: Montevideo, May 12-26, 1 case.

YELLOW FEVER.

Colombia: Barranquilla, June 8-16, 40 cases, 18 deaths; Cartagena, June 1-13, 3 cases, 3 deaths.

Cuba: Havana, June 13-20, 8 cases, 3 deaths; Santa Clara, June 21-25, 4 cases.

Mexico: Vera Cruz, June 16-23, 9 deaths.

CHOLERA.

India: Bombay, May 29 to June 5, 51 deaths; Calcutta, April 28 to May 5, 71 deaths.

PLAGUE.

Arabia: Aden, June 2-9, 11 cases, 7 deaths.

China: Hongkong, May 19 to June 2, 170 cases, 157 deaths.

Egypt: Port Said, May 28 to June 4, 135 cases, 57 deaths.

India: Bombay, May 28 to June 5, 131 deaths; Calcutta, April 28 to May 5, 216 deaths; Karachi, May 27 to June 3, 16 cases, 12 deaths.

Japan: Formosa, Tamsui, May 1-31, 379 cases, 279 deaths; Osaka, June 12-15, 1 case; Shidzuoka, June 12-15, 1 case.

Change of Address.

Dr. C. Ampt, from 1067 to 1156 Pearl St., Cleveland, Ohio.

Dr. F. Von Antenried, from New York, N. Y., to care Dr. Chapman, Cheboygan, Mich.

Dr. C. P. Aling, from 701 Congress St., Chicago, to Blue Earth, Minn.

Dr. R. H. Burrell, from Ann Arbor to Manistique, Mich.

Dr. C. Bock, from Ft. Wayne, Ind., to Petoskey, Mich.

Dr. J. R. Birkeland, from 669 Jackson Boul., to 1169 N. Spaulding Ave., Chicago.

Dr. J. R. Ballinger, from 511 Adams St. to 627 Grand Ave., Chicago.

Dr. N. I. Barron, from Adj.-Gen.'s Office to 1828 G St N. W., Washington, D. C.

Dr. M. M. Beers, from Chicago to Stevensville, Mich.

Dr. L. P. H. Bahrenburg, from Pemberville, Ohio, to cor 19th Ave and 83d St., Bath Beach, Brooklyn, N. Y.

Dr. J. W. Carpenter, from 908 E. McMillan St., Cincinnati, Ohio, to Rock Ridge, Watch Hill, R. I.

Dr. C. Cone, 70 Park Ave, Asheville, to Green Park Hotel, Green Park, N. C.

Dr. J. H. Crawford, from Martin to City Hospt., Augusta, Ga.,

Dr. S. C. Carson, from London, Eng., to Greensboro, Ala.

Dr. W. F. Carver, from Doud Bldg. to Oleson Bldg., Fort Dodge, Iowa.

Dr. B. J. Callahan, from Dakota City to Humboldt, Iowa.

Dr. J. C. Davis, from Iron Duff, N. C., to Jackson, Texas.

Dr. A. M. Earel, from Bloomington, Ill., to Alma, Neb.

Dr. A. B. Engstedt, from Denver, Colo., to 1711 Dodge St., Omaha, Neb.

Dr. F. F. Fowle, from 213 S. Hoyne Ave., Chicago, to So. Milwaukee, Wis.

Dr. O. H. Foerster, from Philadelphia, Pa., to 239 29th St., Milwaukee, Wis.

Dr. R. N. Filiatreau, from 643 2nd St. to 17th and Bank Sts., Louisville, Ky.

Dr. D. V. Gleysteen, from Dubuque, Iowa, to Holdrege, Neb.

Dr. B. F. Gay, from Price to Tilden, Neb.

Dr. E. H. Garrett, from Fresno to 349 N. Main St., Los Angeles, Cal.

Dr. H. B. Graeser, from Des Moines to Kensett, Iowa.

Dr. E. C. Hixon, from Cambridge to Nonquit, Mass.

Dr. A. S. Hudson, from 230 Tremont St., Boston, to 39 Channing St., Newton, Mass.

Dr. G. Hinsdale, from Philadelphia, Pa., to The Nonantum, Kennebunkport, Me.

Dr. S. D. Hosford, from 3419 W. 31st Ave. to 2801 Douglas Pl., Denver, Colo.

Dr. F. L. Hupp, from Wheeling, W. Va., to Hulett's Landing, Lake George, N. Y.

Dr. W. H. Johnson, from 107 Wentworth St., Charleston, S. C., to Univ. of the South, Dept. of Surg., Sewanee, Tenn.

Dr. O. A. Johnson, from Drawer N to Drawer 1111, Kansas City, Mo.

Dr. J. F. Kearns, from Evans to La Junta, Colo.

Dr. O. A. Kellogg, from Owasa to Blairsburg, Iowa.

Dr. A. O. J. Kelly, from 1934 to 1911 Pine St., Philadelphia, Pa.

Dr. I. B. Lyon, from 75 Niagara St. to 531 Franklin St., Buffalo, N. Y.

Dr. F. T. Leys, from 42 Clifford St. to 138 Lafayette Ave., Detroit, Mich.

Dr. J. M. Littlejohn, from Kirksville, Mo., to 405 Washington Boul., Chicago.

Dr. W. W. Lynch, from Galveston to Plano, Texas.

Dr. R. K. Morton, from Baltimore, Md., to 4421 Samson St., Philadelphia, Pa.

Dr. O. F. Maxon, from Chicago to care Wabash Ry. Hospt., Springfield, Ill.

Dr. C. P. Murrell, from 1322 Market St. to City Hospital, St. Louis, Mo.

Dr. J. R. McCurdy, from Philadelphia, Pa., to West Penn. Hospt., 28th St., Pittsburg, Pa.

Dr. E. W. Meis, from Zwingle to Dyersville, Iowa.

Dr. O. A. Newhouse, from Battle Ground to Hillsdale, Ind.

Dr. R. G. Olson, from 948 S. Robey St., Chicago, to 56 Erickson St., Muskegon, Mich.

Dr. R. R. Price, from Pittsburg, Pa., to New Cumberland, W. Va.

Dr. J. C. Potter, from Lombard St. to 1113 Lombard St., Philadelphia, Pa.

Dr. C. R. Park, from 308 Washington Ave. to Board of Trade Bldg., Scranton, Pa.

Dr. J. M. Roadman, from 131 W. College St. to 835 Holly Ave., St. Paul, Minn.

Dr. G. M. Roberts, from Eureka to Lake, Ind.

Dr. A. L. Sherman, from New York to East Chatham, N. Y.

Dr. W. G. Schauffler, from Lakewood, N. J., to The Wannbek, Jefferson, N. H.

Dr. J. C. Sessions, from 2434 Stevens St. to 2518 3d Ave. S., Minneapolis, Minn.

Dr. E. R. Steen, from Joliet, Ill., to Wheatland, Ind.

Dr. R. E. Stone, from 1 Austin St., Buffalo, N. Y., to care H. B. R. & E. R. R., Hammond, La.

Dr. W. J. Stapleton, Jr., from 57 Howard St. to 176 Lafayette Ave., Detroit, Mich.

Dr. T. J. Thorson, from 2422 Wabash Ave., Chicago, to Scandinavia, Wis.

Dr. J. M. Tirrell, from 526 W. 28th St. to 3339 Park Ave., Minneapolis, Minn.

Dr. M. B. Tinker, from 1533 Pine St., Philadelphia, Pa., to Johns Hopkins Hospital, Baltimore, Md.

Dr. A. M. Underwood, from Lancaster, Pa., to Grove Beach, Conn.

Dr. D. W. Van Gilder, from 740½ W. Adams St., Chicago, to 1307 Welton St., Denver, Colo.

Dr. R. H. Wright, from Charlottesville to Petersburg, Va.

Dr. J. H. Woodward, from New York to "Midwood," Long Lake, N. Y.

Dr. H. G. Wood, from 912 N St., Washington, D. C., to 125 N. Maryland Ave., Atlantic City, N. J.

Dr. W. F. Ware, from Bloomfield to Moulton, Iowa.

Dr. W. C. Williams, from Washington, D. C., to Rawley Springs, Va.

Dr. M. H. Yeaman, from Henderson to care Central Ky. Asylum for Insane, Lakeland, Ky.

THE JOURNAL OF THE
AMERICAN MEDICAL ASSOCIATION

61 Market Street : : Chicago, Ill.

Cable Address: "Medic, Chicago"

Subscription price: Five dollars per annum in advance

Postage in the United States and Canada, Mexico, Hawaii, Guam, Porto Rico, and the Philippines, free; foreign postage, $2.50. Subscriptions may commence at any time. Volumes begin with the first issue of January and of July.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

The qualifications for membership require that the applicant be a member, in good standing, of a state or local medical society entitled to send delegates to the annual meeting of the American Medical Association. A list of these societies will be sent on request. Applications must be accompanied with a certificate showing that the applicant is a member of a recognized society, and should be sent with the annual dues—five dollars—to the treasurer, Dr. Henry P. Newman, 100 Washington Street, Chicago. Members receive The Journal free. Subscribers to The Journal may become members of the Association without additional expense if they are members of medical societies recognized by the Association. Those desiring to have their names transferred from the subscription to the membership lists should send certificates as above, with a receipt for their subscription to The Journal, covering the current fiscal year.

FISCAL YEAR.

The fiscal year of the American Medical Association is from January 1 to December 31; and the annual dues paid by a new member cover only the fiscal year, no matter at what time of year the membership is obtained. Those who pay their dues and join the Association at the annual meeting in June, for instance, pay only for the fiscal year which ends with the December following, and the annual dues for the following fiscal year are payable the succeeding January, at which time the treasurer sends a statement to each member. Such members, however, are entitled to The Journal for the full year, even though the membership be not continued.

PAPERS READ AT THE ANNUAL MEETING.

"Every paper received by this Association and ordered to be published, and all plates or other means of illustration, shall be considered the exclusive property of the Association. . . The Board of Trustees shall have full discretionary power to omit from the published transactions, in part or in whole, any paper that may be referred to it by the Association or either of the Sections, unless specially instructed to the contrary by vote of the Association." *(From Article V of the By-laws.)*

NEWS.

Our readers are requested to send us items of news of a medical nature, also marked copies of local newspapers containing matters of interest to members of the medical profession. We shall be glad to know the name of the sender in every instance.

ORIGINAL PAPERS.

Articles are accepted for publication with the understanding that they are contributed solely to this journal.

COPYRIGHT.

Matter appearing in The Journal of the American Medical Association is covered by copyright, but as a general thing, no objection will be made to the reproduction of anything appearing in its columns if proper credit be given.

CONTRIBUTIONS TYPEWRITTEN.

It will be satisfactory to all concerned if authors will have their contributions typewritten before submitting them for publication. The expense is small to the author—the satisfaction is great to the editor and printer. We can not promise to return unused manuscript.

Half-tones, zinc etchings and other illustrations will be furnished by The Journal when photographs or drawings are supplied by the author.

ADVERTISEMENTS.

Advertising forms go to press eight days in advance of the date of issue. Therefore, in sending in copy, time should be allowed for setting up advertisements and for the sending and return of proofs. Advertising rates will be made known on request.

CHANGE OF ADDRESS.

In ordering a change of address it is important that both the old and new addresses be given.

REMITTANCES.

Remittances should be made by check, draft, registered letter, money or express order. Currency should not be sent, unless registered. Stamps in amounts under one dollar are acceptable. Make all checks, etc., payable to "Journal American Medical Association," except those for annual dues. These should be made payable and sent direct to the Treasurer, Dr. Henry P. Newman, 100 Washington Street, Chicago.

The Journal of the American Medical Association

VOL. XXXV CHICAGO, ILLINOIS, JULY 28, 1900. No. 4.

Address.

LARYNGOLOGY AND OTOLOGY.

ADDRESS OF CHAIRMAN.*

CHRISTIAN R. HOLMES, M.D.
CINCINNATI, OHIO.

It gives me much pleasure in opening this session of the Section of Laryngology and Otology to note the proportions to which these specialities have grown. They are no longer the weak sprouts from the parent trunk, but have become sturdy branches bearing rich fruit. As the branch, however, can not flourish unless it is in healthy communion with the parent tree, no more can these specialties bring forth the best results unless their devotees are well grounded in and continue to keep in close touch with their great parent—General Medicine. They have even grown to be such sturdy children that at times they can not sit together, for on February 3, of this year, the Laryngological Society of London unanimously passed the following resolution: "That it is desirable that at all international congresses there shall be full and separate sections for laryngology and otology." Whether the youngest child, rhinology, is to sit alone, or be taken under the wing of one of the other sections, and if so, which one, is not mentioned.

LARGER RECOGNITION BY MEDICAL COLLEGES.

This development has been in the face of many difficulties, and the lack of recognition of the value of these branches and the inadequate provision of teaching facilities is still apparent. Even in scientific Germany, which so freely gives state support to every interest of medicine, and with no stinting hand bestows honor and compensation upon her intellectual sons, in order that they may be able to give their best efforts and years to science and indirectly aid the prestige and prosperity of the nation—even here we find that these departments are not accorded their proper standing in the university curricula. Particular attention has been called to this by Prof. A. Barth, at his induction as professor at the University of Leipsig last July. At present it is not compulsory in the German Empire for the medical student to include otology, laryngology or rhinology in the examination for his degree. Ophthalmology is classed with the surgical division: said division being separated into four parts, of which three are given to surgery and one to diseases of the eye; it is to be hoped that in the near future similar provisions may be made for our triad. It is true that Germany is well provided with splendid clinical facilities for these branches—filled with an abundance of surgical material. Perhaps there would be less if all her physicians were compelled to acquire at least a rudimentary knowledge and fair appreciation of the evils resulting from neglect of affections involving the nose, throat, and ear.

Professor Barth has formulated the following propositions:

1. Every university should have a chair for these departments, with the necessary teaching facilities, i. e., a clinic, a polyclinic, and a laboratory. 2. The occupant of said chair shall have a seat and voice in the medical faculty. 3. It shall be obligatory upon students to attend the lectures and pass an examination in the diseases of the ear, nose, and throat.

Considering the above conditions, we have cause to congratulate ourselves upon the position accorded these branches in this country. Nevertheless, let us not be too self-satisfied, for it is still a fact that with few exceptions these specialties receive far less didactic and clinical attention than one is led to believe by looking over the various college announcements. A year ago I made special inquiries in this direction and was surprised to find how few lectures were devoted to this branch in some of our foremost colleges—a condition partly due to the fact that the science of medicine is steadily growing, and there is not time to qualify in all departments.

PROGRESS SHOWN BY LITERATURE AND INSTRUMENTS.

That the activity in this special field is ever increasing, is evident by the amount of literature upon this subject which has appeared during the past year. This includes several hundred contributions to journals, in addition to larger works briefly outlined below.

ENGLISH.

D. Braden Kyle, "The Diseases of the Nose and Throat," a work that has at once been accorded a high rank both in this country and England.

The fifth edition of Lennox Browne's classical work, "The Throat and Nose."

"The American Text-Book of Diseases of the Eye, Ear, Nose and Throat." Edited by de Schweinitz and Randall. The last three subjects are to be issued in a separate volume.

C. G. Coakley's "Manual of Diseases of the Nose and Throat."

St. Claire Thompson, "The Cerebrospinal Fluid: Its Spontaneous Escape from the Nose, with Observations on Its Composition and Functions in the Human Subject."

S. S. Bishop's "The Ear, Nose and Throat, second edition.

E. B. Dench's revised edition of "Text-book on Diseases of the Ear."

Drs. Head and Andrews, "The Year-Book of the Nose, Throat and Ear."

James Hinshelwood, of Glasgow, "Letter, Word, and Mind Blindness."

GERMAN.

E. P. Friedrich's "Rhinology, Laryngology and Otology, and Their Relation to General Medicine."

A. Rosenberg's "Diseases of the Mouth, Throat and Pharynx." Second edition.

M. Hajek's "Pathology and Therapeutics of the Accessory Cavities of the Nose."

"Encyclopedia of Diseases of the Ear." Edited by Louis Blau, in Berlin, and contributed to by sixty-one other aurists of note.

Jankau, "Vade Mecum for Specialists in Diseases of the Ear, Nose and Throat."

---

*Presented to the Section on Laryngology and Otology, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

E. Von Bergmann, "The Surgical Treatment of Brain Affections," a work of much interest to the otologist.

Danziger, "Deformities of the Palate and Their Relation to the Nose, Eye and Ear."

Prof. E. Hitzig has contributed a valuable article in Nothnagel's "Pathologie u. Therapie," on "Vertigo."

Dr. R. Kayser, "Diseases of the Lymphatic Pharyngeal Ring." This work was jointly begun by Kayser and the late Professor Gottstein, and first appeared in Heymann's "Handbuch des Laryngologie u. Rhinologie."

ITALIAN.

Prof. Gherardo Ferreri, "Manuale of Therapeutic and Surgical Treatment of the Ear."

Of new instruments and modifications of old ones there are a goodly number, all of them more or less valuable. There is need of a practical hot-air apparatus which will furnish the operator hot air under a pressure of from 5 to 25 pounds, dry or moist, and of any temperature he may desire. Several instruments aiming at this have been produced, but I have not seen any that answer all of the requirements. The great difficulty is that the moment air under pressure is liberated it instantly cools, owing to expansion.

REGARDING DEAFMUTISM.

In England the question has again been agitated whether marriage between deafmutes should not be interfered with. Twenty-three per cent. of deafmutes marry in this country; in Europe from 7 per cent. to 12 per cent. Marriages of congenital deafmutes result in 12 per cent. of deafmute children. The percentage of deaf-born children has been placed by various authors at from 30 to 48. These statistics, based largely on the statements of parents, are far from reliable, and the percentage no doubt is much too high. We know to-day that many children become deaf at a very early period of their existence, through inflammation of the middle ear, the direct result of catarrhal changes, or secondary to inflammation of adenoids; if the deafness occurs during the first six months, then it is generally assumed to be congenital. Kerr Love states that he found no special physiognomy to mark deafmutes excepting that in 75 per cent. the appearances characteristic of postnasal growths were present. I have made a careful examination—by mirror where possible, otherwise by touch—of 450 deafmutes in the Illinois State Institute at Jacksonville and found an abnormal development of the third tonsil in 231, or over 50 per cent.

RECENT PROGRESS IN THERAPY.

Favorable results from solar rays as a healing agent in tubercular ulcerations of the throat have been reported by A. Abrahams. Heroin still continues to gain in favor as an anodyne remedy in coughs and irritation of the mucous membrane of the respiratory tract.

Protargol has also come to stay. The best results from its use are obtainable in chronic pharyngitis and atrophic rhinitis, in 1 per cent. solution; and in 5 per cent. solution in empyema of the antrum of Highmore.

Nirvanin, the chlorid of orthoform, is recommended as a local anesthetic and convenient substitute for cocain. It is claimed by Luzenberger to be non-toxic, and can be used in 10 per cent. solution. Its claims for recognition must, however, await more extensive trial.

Rethi recommends the negative air-douche as an aid in diagnosis and treatment of disease of the accessory cavities.

Whether to use heat or cold in acute inflammation of the mastoid is still under discussion. On the whole it appears that the advocates of the application of cold have been rapidly losing ground. I am a firm believer in the application of heat, but I do not apply it by means of hot bags or poultices—limiting it to the very frequent use of large quantities of water at a temperature of 110 to 120 F. as a douche in the external canal, the elevation of the douche to be only enough above the ear to cause a free flow.

Matthaei, of Danzig, recommends as an important aid in the treatment of affections of the nose, throat and ears, deep inspirations—to the very limits of inhalation—with closed mouth, and with retention of the respired air for 1/4 minute, or if walking, during six or eight paces. The exercise should be continued as long as possible.

The use of formalin in weak solutions is still undetermined. In the treatment of vegetable parasites of the mouth the use of alcohol in 50 per cent. solution has brought out most flattering reports. I have used it in my practice during the past 6 months in the above-mentioned strength as a mouth wash and gargle; in full strength as a spray in chronic inflammation of the nose and pharynx, and in the postnasal douche in the strength of one of alcohol to five of water—with sufficiently good results to warrant further investigation.

Fischerich has again brought forward the intratympanic injection of a 2 per cent. aqueous solution of pilocarpin muriate in middle-ear sclerosis, beginning with 6 drops and gradually increasing to 16. From 30 to 50 daily injections constitute the course. His results in 120 selected cases have been very satisfactory.

E. Baumgarten advocates Schleich's method of infiltration combined with local cocain anesthesia in operating upon deviations and ridges of the septum, as it reduces the amount of hemorrhage. That this method is inferior to the use of suprarenal extract and cocain is evident to all who have used the latter.

Suprarenal extract is a most valuable acquisition to our list of therapeutic agents, but is still on probation to determine its real value. Its field of usefulness is much restricted by the tendency to hemorrhage hours after its use. Dr. Mayer rightly maintains that it is better to have whatever loss of blood there is to be at the time of the operation, when the operator is still present with all facilities at hand to control it, if need be; than to invite its occurrence some hours later, when skilled aid may be hard to find. It is well enough to bear the following points in mind, as given by Dr. W. H. Bates:

1. The solution of suprarenal extract should be freshly prepared for each operation, as after 3 hours at 70 F. it usually shows a change in color and becomes less active. 2. We can not show a percentage of strength with any degree of accuracy, as we do not know the amount dissolved. 3. It soon becomes offensive from the growth of bacteria and may then cause infection. 4. The activity of the suprarenal extract is lessened by mixing it with other substances, including cocain. 5. Dr. J. J. Abel has isolated the active principle of the suprarenal, which he finds to be an alkaloid, and has named it epinephrin. The bisulphate of epinephrin in about 1 per cent. solution is active and non-irritating and is said not to undergo decomposition.

As an anesthetic, ethyl bromid has been both praised and condemned. The chief argument against it is that its action only lasts from 2½ to 3 minutes. A fresh preparation must be used each time, as it is very volatile and liable to decomposition, causing changes which render its use unsafe.

G. P. Head, in the "Year-Book of Nose and Throat," states that two deaths have been reported from chloroform during adenoid operations. Three years ago I encountered a number of adenoid cases where the anesthetic caused unpleasant, and in a couple of instances, alarming symptoms. The cases had all been properly prepared by rest and diet before the operation. Since then I have used exclusively Merck's chloroform, and have never encountered any unpleasant symptoms.

PROGRESS IN ETIOLOGY, DIAGNOSIS AND TREATMENT.

Danziger has called our attention to the fact that persons with defects of the membrana tympani might, while diving or swimming, have the water enter the perforated ear with such force as to cause dizziness and nausea, after the manner experienced by some patients when their ears are being syringed, and that this condition may sometimes be the real cause of the patient's drowning. There being no visible proofs, death is generally given as due to heart failure or cramps.

Whether Graves' disease is due to an affection of the thyroid gland or of the nervous system appears still a subject of speculation.

Guye, Lannois and Tournier have reported upon agoraphobia and believe disease of the ear to be a causative factor.

Rischawy calls attention to the fact that while inflammation of the inferior turbinated is most frequently the cause of tear-sac affections, chronic inflammation of this duct can result from hypertrophy and pressure of the middle turbinated body—often favored by dehiscence of the bony canal at this point.

A point of much interest, and one that it would be desirable to have verified by other observers from different sections of the country, is brought out by E. C. Ellert, of Tennessee, who states that adenoids do not occur in the negro. It has also been claimed that the negro is exempt from granular conjunctivitis.

Rhinologists are still at variance as to the origin and treatment of ozena. As to origin, it appears to be narrowing itself down to one of two causes: Some believe it to be of trophic origin, perhaps having its point of beginning in the bone. Cozzolino believes the bacillus mucosus develops simply because of the favorable field, and brings about two of the most disagreeable symptoms —fetidity and crusts. There are, however, many who believe that ozena is only a secondary manifestation due to disease of the accessory cavities. Where local treatment only has been adopted, cupric electrolysis appears to have yielded the best result. In the treatment of hypertrophic conditions in the nose there has been a steady decline in the use of the galvanocautery. While nearly all admit that the galvanocautery has a limited field of usefulness in intranasal work, it is rapidly being supplanted by clean, surgical operative procedures.

Kicer's article on the accessory sinuses, based on 200 post-mortems, is highly instructive in showing how frequently the sinuses are involved; but the most important point of all is his conclusion drawn from so much material—that puncture of the frontal sinus from the cavum nasi is a decidedly risky procedure, the probe as a rule entering the sinus only after piercing several cells, and in a number of instances penetrating the lamina cribrosa and entering the cranial cavity without the operator knowing that the probe had taken the wrong direction.

Treatment of chronic empyema of the maxillary antrum and sphenoid sinus is still yielding but little satisfaction. Whether the transplantation of epidermal strips by Thiersch's method, into the thoroughly curetted cavity, will bring us better results, still remains to be proved. I saw Dr. Jansen make a number of these operations last autumn and from a surgical standpoint it seems this method ought to yield a much greater percentages of cures than the old way. Jansen encountered much difficulty in preventing the accumulation of secretions causing maceration and often loss of the transplanted flaps. This marvelous operator now enters the sphenoid cavity by means of long narrow chisels, passing through the posterior wall of the antrum into the sphenoid cavity. I performed the operation a number of times upon the cadaver, but must say that I have scarcely the courage to do it upon the living when handicapped by bleeding, etc., preferring to make the opening through the nose.

The chiseling off of the entire anterior wall of the frontal sinus, as practiced by Kuhnt, Grunnert and others, appears to me, excepting in rare cases, an unjustifiable operation because of the resulting disfigurement, as the frontal sinuses can be thoroughly entered from either side of the median line through the floor and anterior wall of the cavity.

Hendelsohn's carefully conducted experiments to demonstrate the reaction of tonsillar tissue to pulverized substances, when blown on or injected into their substance, led him to the conclusion that the tonsils are not protective organs, but, on the contrary, being receptacles of infective germs, their removal, if abnormal, is indicated, not only in the interest of easy respiration and deglutition, but to obviate infective diseases.

That the operation for adenoids should be radical and under some form of general anesthesia is now the opinion of most operators. That the presence of adenoids adds to the gravity of the disease in diphtheria is shown by Plottier's investigation of the bodies of 38 children who died from that disease. He found adenoids present in 50 per cent.

Jessen refers to the fact that large masses of cervical lymphatics that resist all ordinary methods of treatment disappear promptly after the removal of nasopharyngeal adenoids.

This condition is frequently seen, but I must confess that I never quite realized its full importance as a diagnostic sign until of late, when I operated upon two children in whom this condition was pronounced. Being in daily contact with them I studied all of the symptoms carefully, and noted especially that although the adenoids did not interfere with respiration, the glands on the side of the neck fluctuated very much in size with every fresh catarrhal attack. The glands disappeared promptly and permanently after the operation.

Piffl, who investigated 100 cases of hyperplastic pharyngeal tonsils mostly from Zaufall's clinic, advises in case of the least suspicion of tuberculosis to remove the pharyngeal tonsils at once, and radically; particularly if swollen lymphatic glands are on the neck. At the last meeting of the Gesellchaft der Kinderärzte, in Moscow, Dr. Sack presented this subject in a masterly manner. He believes that the "glandular fever" described by Pfeiffer in 1889 is probably an acute adenoiditis—this condition at times assuming a subacute character with fever, pus-resorption and cough, lasting weeks and even months.

The reported results of operations upon the larynx for malignant growths are very gratifying. Gluck, for instance, reports that in his last 26 operations for carcinoma of the larynx he has had 23 cures. Felix Semon has also published an article giving similar results. Dr. Garelle has perfected an apparatus by means of which he can produce stereoscopic photographs of the condition of the larynx—full credit is given to French of

Brooklyn. F. Von Mangoldt has reported four successful cases where he transplanted costal cartilage into the larynx for the cure of severe stenosis and defects. Dr. Alapi has also reported a case of larynx stenosis cured by skin-transplantation by Thiersch's method. Dundas Grant calls attention to the fact that in a large number of cases laryngeal inflammation is associated with, or secondary to, nasal disease.

The osteoplastic opening of the mastoid after Kuster is still a very recent operation. That it will receive much encouragement at the hands of other operators I believe is doubtful: if used at all it will largely be limited to acute cases, requiring only the classical operation. His claim that the flaps offer a good opportunity for the tampon in case the sinus or dura mater is injured during the operation is not worthy of serious consideration. Many of our German confrères still practice the leaving of a large post-auricular opening after radical mastoid operations. Some are in favor of leaving the opening permanently; while others close it by a plastic operation after one or two years, provided there has been no return of the disease. This opening is very unsightly, especially in men, who can not cover these parts after the manner of women, and excepting in rare cases I fail to see the need of it. In 115 radical operations including the usual variety of cases, I have not found it necessary to leave a single one permanently open, and all have recovered with a canal larger than before the operation, permitting free inspection of every portion of the cavity. The transplantation of skin grafts into the cavity after the radical operation, either by Thiersch's method or pedicled flaps, shorten the process of epidermization very materially; but it still remains to be proved whether or not the hearing power of the ear is less than it would be by the old method; because a thicker epidermis may form over the stirrup and round window. Also whether, in certain cases, the leaving of the hammer and anvil in the radical operation will give better results, remains to be seen by practical demonstration upon a larger number of cases.

NEUROLOGY AND MEDICAL JURISPRUDENCE.

ADDRESS BY CHAIRMAN.

HUGH T. PATRICK, M.D.

CHICAGO.

On assuming the chair of this Section I desire to express my keen appreciation of the honor conferred upon me and my recognition of the disproportion between officer and office to be filled. Knowing full well that neither unusual scientific attainments nor long years of service entitle me to this distinction, I none the less feel free to avow the liveliest satisfaction with my present position. However pleasant may be the approving eye of the public, however gratifying the laudation of medical students, and however dear the affection of grateful patients, surely sweetest of all is the confidence of one's associates: the men who know; the men who can estimate another at his real worth; who can recognize good work and detect superficiality at a glance; who peer into scientific lacunæ and are in a position to note professional backslidings as well as personal merit. When, therefore one is chosen by his confrères to preside at their deliberations, he should feel as does your chairman—grateful, proud and happy.

After a thoroughly honest and rather prolonged effort to prepare a statement of the recent advancements in the branches belonging to this Section, as required by the Constitution, I frankly acknowledge my inability to do so within the limits of an address restricted by law to forty minutes, but which should not exceed twenty. During the last year there has been no single pre-eminent discovery in our department. Advance has been general, accomplished by thousands of workers in many fields, and an attempt to cover this in a short address would either produce a puerile *index medicus* or result in invidious distinctions unworthy of a fair mind and misleading to the reader. Unwilling to deliberately perpetrate either fault, I have consigned most of my work to the much-cheated waste-basket, and shall confine myself to a few suggestions and remarks considered to be germane to this Section, its work and members.

I would first respectfully suggest that the name of the Section might well be changed so as to omit "medical jurisprudence" as an integral component. Early in the movement which brought forth the Section now known as that of Neurology and Medical Jurisprudence, the aim was to include nervous and mental diseases, but the officers and leaders of other Sections, recognizing that much of their best matter might be taken from them, opposed the proposition so strenuously that defeat seemed assured. Rather than capitulate, the promoters promptly executed an orderly and temporary retreat by accepting a Section on Medical Jurisprudence alone, since nobody wanted that, and it was willingly turned over to the neurologists, alienists and medical experts. This was in 1886. In 1890 their second forward movement accomplished the addition, or rather prefixion, of neurology, and for a decade the title has remained unchanged.

An examination of the records for the last ten years shows that in the work of the Section, medical jurisprudence has taken a relatively unimportant position. Of the total 444 papers announced, 64 may be reckoned as belonging to this department, but of these 39 related to the medicolegal relations of nervous or mental affections, and thus would naturally fall to a Section on Neurology and Psychiatry, leaving only 25, or 5.6 per cent. coming to this Section because it was that on Medical Jurisprudence. During the same time 125 papers on topics coming under the general head of Psychiatry, including inebriety, hypnotism and psychology, have been announced; that is, 28 per cent., exactly five times the number on forensic topics, excluding nervous and mental disease. Even without these figures, it must be perfectly evident to any one who has observed the matter at all, that the great strength of this Section lies in its neurologists and alienists—men who are only casually or secondarily medical jurists. In fact, I very much doubt if the subject of medical jurisprudence should be assigned as an entity to any Section of the Association. Would it not be more reasonable and successful to allow and encourage each Section to consider that particular phase of legal medicine which would naturally be of interest and profit to its members? The legal bearings of oöphorectomy are of importance to the gynecologist, while this special surgeon cares little about the forensic relations of cataract, and the neurologist can well afford to ignore both. Furthermore, while nosologicaly, medical jurisprudence may be said to be a well-defined department or branch, be it of medicine or of law, in the practice it has not attained to the dignity of a specialty in either profession. There are practically no physicians who confine their efforts to legal medicine, and the subject is particularly connected with no special line of work. To repeat, then, I would submit to you the question of changing our name to "The Section on Nervous and Mental Diseases," or "The Section on Neurology and Psychiatry."[1]

---

*Presented to the Section on Nervous and Mental Diseases, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

However ambiguous the paternity and connections of medical jurisprudence, there can be no question as to the standing of neurology and psychiatry—speaking of them combined as constituting a single branch of medicine. This specialty is the legitimate child of increased medical knowledge and the inevitable differentiation involved in evolution. At least, no one of those who know best can deny that the specialization of this part of practical medicine is absolutely necessary for the better understanding of nervous and mental diseases and for the best results in their treatment. Yet, strange as it may seem to most of us, there are many physicians who seem to think that, however interesting neurology may be as a study, and even useful in the discovery and elucidation of esoteric technicalities, it has no necessary place, and hence should play no vital part, in everyday practice and teaching—and this in face of the fact that most physicians, surgeons and specialists are almost obtrusively willing to acknowledge their ignorance of the nervous system and to deplore their inadequate instruction as students in its diseases. Since every neurologist and alienist knows this ignorance to be so ubiquitous as to be pathetic, and since he knows, too, that no professor of internal medicine is now thoroughly competent to teach nervous and mental diseases, is it not his duty to the public and the profession to see to it that his specialty is accorded proper recognition in the practice and in the schools? The ophthalmologist is not slow to insist that no general practitioner, that no general surgeon, is warranted in operating for cataract. With equal propriety the gynecologist frankly asserts that certain operations must be attempted only by the man of peculiar training and skill. No one will say that more time, talent or industry is necessary for the making of a good oculist than of a good neurologist; yet, while our eyes, thank God! are cared for by the oculist, the nervous system in the public, in the profession and in the medical school is largely attended to by any indifferent man. To be sure, in the schools may generally be found a clinical or associate chair, simply a sop to common sense, while from other chairs the neurologic teaching of a quarter of a century ago goes merrily on.

Any neurologist to whom it comes to quiz the graduating class of a medical college or a collection of practitioners, will find the trail of the serpent over them all —the serpent of ignorance let loose by professors of general medicine, gynecology, surgery and what not—who are allowed by medical faculties to dabble in subjects with which they are only half acquainted or of which they have no knowledge. Here is the whole explanation of the crude and misty ideas of neurology which hamper rather than help the young practitioner.

But while insisting on the absolute necessity of the recognition of neurology in schools, if the young physician is to have knowledge of nervous disease commensurate with his needs, it may not be amiss to remind the exponents of our department that the class-room is not a court for airing anatomical minutiæ, unconfirmed discoveries and recondite theories, but is the place for the preparation of young men to assume the duties and responsibilities of the practitioner of physic.

Co-ordinate with the art of practical teaching is the art of practical practice, and back of both must be the art of practical investigation. If the position of the neurologist in institutions of learning is to depend on the utility of his teaching, his position in the active profession will rest largely on his usefulness as a practitioner, and there would seem to be some room for improvement in this respect. In some quarters it is almost the fashion to say that the nervous system is marvelous to contemplate and the neurologist a clever diagnostician and very erudite gentleman withal, but that he never cures anything. A most unjust sneer, because he is the means of curing many maladies, but even if he were not, he would still have ample field for usefulness in preventing and correcting the monstrous blunders of his detractors.

And yet, where there is so much smoke there must be some little fire. Are we not too much engrossed in the study of stains, tracts and symptoms? Sworn devotees of the healing art, are we not abusing our energies in the pursuit of new maladies and the mere vagaries of disease? Official healers of men, some of us become veritable pathomaniacs, blind to the patient, seeing only the pathologic process. To get a side light on this subject I have gone to a few of the leading neurological journals. In one year of the *Neurologisches Centralblatt* there appeared 70 original articles and 811 abstracts. Of the original papers only one may be counted as devoted to therapeutics; of the abstracts, 49. In the *Deutsche Zeitschrift für Nervenheilkunde* for a year were 46 original articles, not one of them on treatment. Two volumes—about two years—of the *Archiv für Psychiatrie und Nervenkrankheiten* contained 61 original contributions, of which one was on a therapeutic subject. The *Archives de Neurologie* for a year presented 37 papers, 2 on treatment. In two volumes—two years—of *Brain*, I found 54 originals, none on a therapeutic topic. The *Journal of Nervous and Mental Disease* for a year contained 46 originals and 222 abstracts. Of these, no original was devoted to therapeutics and only 25[2] of the abstracts were. That is, in six of the leading neurological journals of the world only 2.2 per cent. of the original contributions related to the cure or alleviation of disease, and counting the abstracts, largely taken from journals not neurological, the proportion of therapeutic topics reached only 5.4 per cent. Do not these figures show that in our eager search for knowledge and praiseworthy desire to be scientific, we are neglecting our more utilitarian function?

The proposal made by your chairman of 1897,[3] that the secretary should be continued in office for two years or more, seems to be a wise one—although it ill becomes the present chairman to say so—and I wish to add a suggestion or two which seem to me to be along the same logical line. As a secretary is sure to profit by his own experience and by familiarity with the men interested in the work of the Section, so may he profit by the experience and personal knowledge of previous officers and of strong men of the Section. I freely confess that as secretary and as chairman, I have been keenly alive to the responsibility of the position, and have been most uncomfortably conscious of my incompetency to make perfect preparation for the meetings, and thus attain ideal results. Even the Pope, graduated into his position by virtue of pre-eminent genius and after years of laborious apprenticeship, prayerful education and ripe experience, is considered to be infallible only after mature consultation with the college of cardinals. Hence, it seems to me eminently fit and practicable, as conducing to wiser decisions, more effective policy and particularly to compactness of organization, that before the adjournment of each meeting there should be a consultation of the incoming officers with the executive committee and a few of the wiser and more experienced members. Not only would such consultations contribute materially to the success of the following meeting, but a repetition of them, I am sure, would materially aid in making this Section one of the strongest in the Association, and the minutes of such committee meetings, carefully made and preserved, would be invaluable to incoming officers year after year.

---

[1] This suggestion was carried out, and the name changed to Section on Nervous and Mental Diseases.

[2] Twelve of t [illegible]

[3] Dr. W. J. [illegible] ch

And this leads me to another point. When, raw and callow, I first assumed the duties of secretary, I was astonished to learn that not a line of record, correspondence, instruction, precedent, hint or suggestion descended to me from my predecessor. For fourteen years motions had been made, amended, lost, carried and had quietly slipped into oblivion, leaving no trace behind. Policies had been endorsed and rejected, resolutions adopted, committees had been appointed, had reported and been discharged, and not a minute made. I submit to you that this is a slipshod way of conducting affairs and not calculated to breed good executives.

Without your sanction I have ventured a small beginning. As retiring secretary I transmitted to Dr. Pearce the complete correspondence of two years, with a short series of programs, upon which were marked those men who had been present to read papers. You know there is a certain small contingent of members who are always willing to announce papers and as regularly default. They are to be religiously shunned, but the secretary can not do this unless he knows who they are. I have also purchased for the Section an indexed blank book, in which the secretary may make such records and entries as may seem proper and advisable. And as a token that, although our place of meeting and officers change annually and our active membership is more or less floating, our organization is yet permanent and we a unit, I beg to present to the Section a plain gavel, suitably marked, which I hope may descend from chairman to chairman through many successive years of ever greater prosperity of the Section on Neurology and Medical Jurisprudence.

Original Articles.

POST-FEBRILE INSANITY AND ITS TREATMENT.*

FRANK PARSONS NORBURY, M.D.

JACKSONVILLE, ILL.

All disorders that affect general nutrition of the body may affect the mind. The brain, the organ of the mind, is sensitive to nutritional changes, and when these are profound they may permanently affect the mind's nature. The imperceptible fluctuations of brain nutrition have concomitant fluctuations of mental action, and these physical processes, if carefully studied, reveal to us that there is physical basis to mind. The physiology of mind need not be discussed here nor need we wander into the psychologic labyrinths to study the relationship of body to mind. It is only necessary to state, whatever is the organic process of mental action, its basis is, like that of other elements, in the cell. The brain-cell has its organization and its nutrition; perversion of either causes disturbance of function. This disturbance when changing the routine and characteristics of an individual mental life, we sometimes call insanity. But do not let me have you infer that insanity is alone perversion either in organization or nutrition of brain-cells, for that would imply that mind essentially was the direct function of the brain, when in reality mind is a constitutional function, a function of the organism as a whole; that is, that every organic function of the body has representation primarily or secondarily in the whole we call mind. Hence, in dealing with mind disease we are dealing with the body in disease. This fact should impress the metaphysically inclined alienist with the thought that to treat the mind we must treat the body, and he who would succeed as an alienist must first, last, and all the time be an internalist, in touch with the progress being made in internal medicine. Especially is this necessary in handling the mental disorder, post-febrile insanity, which we are now to consider.

In view of the foregoing remarks, there is a cardinal principle in internal medicine which we may take for our text, because of its applicability, and that is, "that disposal of the waste products is essential to the health of the cell." Healthy metabolism is the keynote to bodily health. Burchard has shown that abnormal metabolism always precedes infection and what renders possible the development of disease is not the chance meeting of man and microbe, because we are constantly assailed by pathogenic bacteria, but it is due to the diminished resistance—the modification antecedent to nutrition—the failure of nutrition; in short, abnormal metabolism which permits infection to enter, to remain undisturbed and to grow and multiply. The morbid opportunity is grasped, and nutritive activity being perverted, infection results. The study of infection is one of the recent triumphs of modern medicine and should concern every physician, for the possibilities of practical application derived from the patient and exhaustive researches of the laboratory worker extend to every department of medicine. Welch says, "there is now tolerable unanimity of opinion as to the meaning attached to the terms infection and infectious diseases. Most recent authorities understand by infection the condition produced by the entrance and multiplication of pathogenic micro-organisms within the body. An infectious disease is one which is caused by the invasion and reproduction within the body of pathogenic micro-organisms."

We will not, however, attempt to discuss immunity and susceptibility, and while we will not deny the importance of a thorough understanding of the biology of bacteria, yet we are concerned principally in the effects of infection. Every infection should interest us, and the perplexing problems of infection to-day should be studied that we may contribute our mite to their pathology. Again, as alienists and neurologists, we meet with the clinical results of infection, showing the rôle which the nervous system plays in this field of study. Ernst[1] quotes the conclusions of the exhaustive review made by Mills along this line. They are as follows:

1. Specific infection must be included among the causes of mental diseases and of symptoms which precede, accompany, or follow febrile or other infectious disorders.

---

*Presented to the Section on Neurology and Medical Jurisprudence, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

[1] Twentieth Century Practice, xiii, 200.

2. Much negative evidence can be adduced in favor of acute delirium being due to toxemia, such evidence is afforded by autopsies, which reveal neither gross nor histologic lesions; and in these cases the toxemia probably overwhelms the patient before the production of meningitis or other disease.

3. Analogies to nervous affections, which are known, or believed to be of microbic origin, such as multiple neuritis, myelitis and chorea, favor the view that insanities with similar or related phenomena and lesions are also microbic in origin.

4. The evidence afforded by careful bacteriologic investigations of acute insanity is thus far too meager but shows that various micro-organisms may induce the same or similar types of mental disease.

5. The mental disorders of pregnancy and the puerperal state are probably in a considerable proportion of cases, toxemic, without reference primarily to childbirth; but it can not be regarded as proved that a bacillus of eclampsia or puerperal mania is a sole cause of these affections.

The psychic and nervous troubles, then, which may originate from toxemia are many. The manner of causation is primarily by means of the absorption of products of the various pathogenic processes. The perverted nutrition brought about by the febrile disease makes possible conditions in which certain substances elaborated by the living organism are modified—either by their disproportioned existence, or by reason of this disproportion abnormal substances are allowed to be generated and retained, thereby becoming toxic substances, and produce poisoning more or less severe. "The augmentation of normal substances either by increased formation or retention can induce quite a series of accidents," some of which are uremia, asphyxia, cholemia, etc. Many of the new products resulting from faulty metabolism are capable of producing intoxication. As examples we have eclampsia, coma, epilepsy, etc. This intoxication, or toxemia, is now being exhaustively studied both at home and abroad. The excellent work of Christian A. Herter, of New York, is especially instructive and valuable. Regis has made a clinical study of the psychoses of autointoxication, to which we will refer later.

HEREDITY.

Heredity bears a position in the etiology of post-febrile insanity which, in a sense, may be called tentative, inasmuch as the insanity is not a true heritage in post-febrile insanity. The obscure tendencies only partially revealed under the stress and strain of disease may be the simple result of the toxemia. However, there are certain individuals possessed of a neurotic weakness and a physical instability easily influenced by febrile diseases. This condition, due to a flaw in the germ-plasm, seems to be easily disturbed, either by the febrile process alone or by its toxic products. The result is, certain persons become delirious under moderate fever, others are practically insane during the continuance of infectious fevers, and some women become insane during the puerperal stage at every childbirth. Again, the toxic products of metabolism affect certain individuals profoundly, as in gout, rheumatism, etc. Neurotic temperament is a foundation for alienation following febrile disease. It is an error in breeding, a flaw in generation and about the only true hereditary factor in the etiology of post-febrile insanity.

RESIDENCE AND OCCUPATION.

It has been my experience that residence is a factor in causation of post-febrile insanity, but only as regards location being favorable in the production of the febrile disease. For example, I have seen insanity follow malarial fevers; the home of the individuals being in the malarial belt of Illinois. So-called typhomania is dependent on typhoid fever and this in turn on poor hygiene, municipal or domestic. Occupation is an etiologic factor only in the same relationship.

TYPES.

The nature of the mental disease, post-febrile insanity, varies. It has no distinctive form, varying with individuals, and in the same individual at different times. I had one patient, who, following typhoid fever, had acute mania of a violent type, but following influenza he developed melancholia. The types usually seen in post-febrile insanity are acute mania, acute melancholia, recurrent mania, and sometimes general paralysis. The psychoses of autointoxication are classed by Regis[2] under a single head, "confusional insanity." He says, the psychoses of autointoxication have a special symptomatology and a characteristic type. On this account I wish to briefly state his results, that it may aid us in differentiating types. The symptoms upon which he lays special importance are headache, which is often initial in its feature and may be prolonged throughout the attack. It may be paroxysmal and so severe as to produce delirium. The second important symptom is insomnia, which is also early and constant in its manifestations. Less frequently convulsive attacks are encountered, also pupilary changes, reflexes, increased tremor, irregular pulse, cyanosis, skin changes, flushings, cold extremities and sallow compexion. He classes the cases as follows: 1, simple asthenic confusion; 2, acute and subacute mental confusion; 3, mental confusion with stupor; 4, subacute confusion of a pseudoparalytic type.

The types of post-febrile insanity may in a measure follow the same classification, except that there seemingly is a wider range of alienation in the cases following infectious fevers as compared with those following autointoxication from other sources. The effects of the toxemia, whether it be from the direct action of the pathogenic bacteria or their toxic products, or from autointoxication, are: 1, to depress function, this depression ranging from contusion to profound melancholia with marked delusions; 2, to stimulate function, causing over-excitation of mental processes, delirium, loss of inhibitory control, incoherence, to grave cases of acute mania with profound exhaustion; 3, to impair function by intracellular changes, and finally, to abolish function and produce paralysis. The pseudoparalytic to the true general paralytic state.

The severity of the attack of post-febrile insanity seemingly has no apparent relationship to the severity of the febrile attacks, as I have seen cases of acute mania follow a mild attack of facial erysipelas and a case of mild melancholia follow a prolonged siege of typhoid fever.

Again, the time of the appearance of the insanity may vary; thus, it may appear while there still lingers a vestige of the fever, the delirium of the fever merging into a true insanity. A boy aged 19 who had a mild attack of typhoid fever, running the usual course, developed true insanity four days after his morning temperature reached normal, and his evening temperature only one degree above. Acute mania resulted, from which he recovered at the end of three months. In a case seen in consultation following erysipelas, the mental disease did not develop until five days after subsidence of the fever, and acute melancholia resulted, lasting nine weeks. Another case, following influenza, developed melancholia a week after the febrile attack. We may notice that other sequelæ of fevers develop at the same time that the mental disease is in evidence; thus, in one of my patients phelgmasia dolens and insanity followed typhoid fever. Another case of acute mania following measles in an adult developed pneumonia, and death followed about the fifth day. Another case of measles in an adult, with melancholia, developed acute nephritis, and finally died of uremia. It may be of interest to state here that I have noticed in my experience that occasionally an acute infectious fever attacking a patient already insane, promotes recovery, or temporarily causes mental improvement. Thus in a case of chronic mania after acute lobar pneumonia, the patient recovered his reason, having been insane seventeen years. Another case of acute melancholia had erysipelas, and during the febrile stage was himself in every way; his complete recovery followed speedily after the erysipelas.

---

[2] American Year-Book, 1900, p. 421.

DIAGNOSIS.

The diagnosis of post-febrile insanity under ordinary conditions is not difficult, especially when following typhoid fever, and I may add erysipelas. In typhoid fever, the peculiar typhoid state is stamped upon the individual, and in the great majority of cases, melancholia is the type of insanity. However, I have seen in consultation several cases in which maniacal excitement was especially pronounced, and two cases presenting the physical symptoms of the paralytic form—a pseudoparetic state, distinguished from genuine paresis by the pupilary symptoms, the speech symptoms, and the absence of characteristic vibratory trembling of the tongue, although motor weakness may extend to the facial muscles. Again, the characteristic delusions of paretic dementia were absent, and instead, a mild delirium, with incoherence, was present. Another feature of diagnostic interest is the fact that many cases of beginning post-febrile insanity first manifest mental symptoms at night, being comparatively lucid during the day. Gradually a change is noticed, the hallucinations become more vivid and delusions appear. Delusions of a persecutory nature are more common in cases following typhoid fever, and it not infrequently occurs that suicide follows such attacks. I have known of three suicides in post-febrile cases in private practice; two by drowning, and one by jumping from a window. Post-febrile insanity has a true vesanic foundation and it is to be distinguished from the constitutional degeneracies. This is usually easily done by considering the history and general symptoms presented by the case. What may be termed a pseudoparanoia may result as a sequela of influenza—I have seen in consultation two such cases, in which the delusions were systematized and persistent, but later, with the restoration of bodily health, the delusions gradually faded away and finally disappeared; the patients making good recoveries. The use of modern laboratory methods will cast light upon obscure symptoms in differential diagnosis. A blood-count and microscopic study have been of great aid to me. These, with urinary analysis, should be followed in all cases as a part of the systematic routine of clinical examination.

PROGNOSIS.

The prognosis in all cases of insanity should be guarded, as it is difficult to measure the hereditary factor, and, again, the accidents of mental disease should be considered. In post-febrile mental disease occurring in adults with a good family history, and free from any diathetic associations, the prognosis is generally good. Especially is this true of melancholia, but patients with acute mania exhaust themselves rapidly and the natural exhaustion of insanity added to the already debilitated state of the patient makes the prognosis in such cases guarded. But, upon the whole, the prognosis is good in the average case.

TREATMENT.

The treatment resolves itself into proper care, good nursing, a systematized routine, and good hygienic surroundings. Some cases do well at home, but ordinarily they are better off in a well-regulated hospital or special institution. The nursing is of special importance, and in cases following typhoid fever, the routine should be that observed in the care of ordinary typhoid cases, to which is added the care and protection needed to combat the insane features of the case. A more liberal diet is a feature in the care of insane cases differing from ordinary convalescence from typhoid fever. Bushuyer, a Russian, gives a more generous diet to his ordinary cases of fever than we are accustomed to give in this country. He, probably, is too enthusiastic, yet, experience teaches that a liberal diet can be given, provided we treat the patient and not the disease. In the words of Shattuck, "feed him with reference to his digestive power, rather than solely or mainly with reference to his fever." It is to be expected that both skill and ingenuity will be needed in order to properly feed and nurse a post-febrile case; to this end all of our efforts should be centered. It is imperative that due regard be given to elimination, and a proper regulation of the secretions; then as nutrition becomes re-established, the patient will gain in weight, and gradually the mental symptoms will clear up. In many cases it becomes necessary to enforce rest, and in acute mania this must be assiduously secured, else the patient exhausts himself speedily. A modified rest-treatment is to be recommended in cases of a melancholy type, especially after convalescence seems to be pending. There should be no "hard and fast rule" as to rest-treatment; it should vary with the needs of the patient. Massage is indicated in many of the apathetic cases; it promotes nutrition and in some cases will induce sleep. In the true cases of autointoxication, elimination must be promoted by liberal use of aperients, diuretics, and, if necessary, brisk cathartics. The urine should be carefully measured and an analysis made so as to determine its quantity and quality. The percentage of urea should be observed and a microscopic examination made to determine the presence of casts. I saw during the past winter two cases, in consultation, both of whom presented symptoms of autointoxication and had been treated as such, but a more careful diagnosis showed acute nephritis. Uremic poisoning had caused the mental symptoms. Plenty of water is indicated in such cases, both internally and externally. In my hospital cases, I urge a sponge-bath daily, followed by brisk rubbing. Good drinking water is urged on all occasions. As to drugs, I use only such sedatives as are absolutely necessary. Of these, opium and hyoscyamus I use principally, and only in sufficient quanity to produce the sedative effect. Most cases of post-febrile insanity demand tonic treatment from the beginning; iron in easily assimilated form and arsenic are indicated. The anemia is best met by the use of arsenic; iron and strychnia are valuable adjuvants. Other tonics, especially the mineral acids combined with nux vomica and pepsin, or the malt preparations with tonics, are also valuable. In adolescent female cases iron and manganese make an excellent combination.

As convalescence progresses, some active exercise may be encouraged, such as walking, riding and light gymnastics. When convalescence is established, and not until then, travel may be suggested. Traveling with a convalescent post-febrile case is not safe, and suicides occur among such patients.

PRACTICAL PHYSIOLOGY OF THE DIGESTIVE ORGANS.*

A. L. BENEDICT, A.M., M.D.
Professor of Physiology and Digestive Diseases, Dental Department. University of Buffalo.
BUFFALO, N. Y.

In this paper it is the intention to allude to some well-known physiologic principles and to describe certain details not so well recognized, all with reference to their application in digestive practice. It is obvious that such a consideration, to be even fairly brief, must be disjointed and incomplete.

1. *The Mouth and Salivary Glands.*—The importance of mastication and insalivation is an old story. While admitting it, I am skeptical as to the chemical value of salivary digestion. While, by very elaborate mastication of dry cereals, J. H. Kellogg has been able to accomplish the conversion of considerable quantities of starch into sugar, as ordinarily carried out, even by careful eaters, only the small proportion of soluble starch of the very light test-meal is digested. Some animals are quite lacking in ptyalin, and I believe the principal function of the mouth and salivary glands to be mechanical. It may be of interest to know that pytalin will convert small quantities of cane-sugar into a sugar that reduces an alkaline solution of $CuSo_4$. Several investigators have conducted elaborate experiments to ascertain just how much HCl is required to inhibit carbohydrate digestion by pytalin. In general, these investigations may be summed up as follows: Pytalin digestion normally continues during the first hour of gastric digestion, or, in fact, till HCl secretion reaches its normal maximum.

To what extent is it necessary to administer artificial diastase in failure of starch digestion in the stomach? In view of the fact that, normally, only small quantities of starch are digested before the intestine is reached, it would seem rational to conclude that the mere failure of pytalin digestion is not an indication for diastase. If the starch simply does not digest, as in hyperchlorhydria, let it alone till the pancreatic ferment strikes it. If it ferments, treat the bacteria and fungous activity in the stomach, preferably by administering HCl. If there is a well-marked indication for superalimentation, then there exists the only possible indication for artificial diastase, unless the amylopsin is lacking, and this condition I have diagnosed only once, in a case of Addison's disease.

Regarding sugars, there is a physiologic puzzle that awaits a solution. Starch is digested only into maltose either by pytalin or amylopsin. Maltose is a double hexose—$C_{12}H_{22}O_{11}$—like cane-sugar, and lactose, both of which are foods of considerable quantitative importance. All of them are converted into dextrose and levulose by the inverting ferment of the intestinal glands. Certainly some of these double hexoses must be absorbed before the intestine is reached. Do they exist as such in the portal blood? Are they changed in passing the gastric epithelium? Is there a hepatic or hemic ferment to convert them into glycogen? Do they pass through the liver into the general circulation?

The activity of the salivary glands in excreting such substances as the iodids has been adapted to the test of gastric absorption. After administering a capsule of KI, the drug is normally detected in the saliva within fifteen minutes. A delayed appearance has been considered proof of delayed gastric absorption. In one of my patients, in whom it appeared only after an hour, I found that the capsule would not dissolve in water, but required digestion, so that the iodid test was really one of proteolysis. In some very serious cases, I have found that the iodin went the round of the circulation and was eliminated in the saliva with normal promptness. On the whole, the test is so artificial and depends on so many unknown factors that it has little practical value.

2. *The Esophagus.*—Some years ago, while listening for deglutition murmurs at the cardia, it occurred to me that the time of the passage of water through the esophagus, between the elevation of the hyoid and the sound at the cardia, might afford an indication of the rate of peristalsis in general. With a little experience, the average time will be learned—it is about 8 seconds—and a marked delay is almost invariably associated with gastric atony, dilatation, ptosis or intestinal sluggishness. However, I have recently examined a case in which the esophageal peristalsis was normal, but in which there exists marked constipation.

The esophageal mucus resembles that of the cervix uteri, in being tenacious and stringy. It is a most excellent lubricant, and it is entirely unnecessary to lubricate the stomach-tube, though it is well to moisten it. The appearance of esophageal mucus in considerable quantity sometimes indicates that the tube has kinked, and explains the failure of lavage. In a recent case, the gastrodiaphane, having a rigid tip two inches long, turned in a roomy esophagus, from which 250 c.c. of slime was regurgitated during the attempt to pass the instrument through the cardia. The normal esophagus will just about admit a No. 11 tube, although some will allow the passage of food, or at least a breaking of the vacuum beside the tube. Patients with roomy esophagi have usually been in the habit of bolting their food half masticated. A practical question in this connection is as to how large an object a baby can swallow. He has been seen playing with some article which has disappeared; has it gone into the stomach? Even infants may take an adult-size stomach-tube, and I am inclined to think that they may swallow smooth and approximately spherical objects of a diameter up to one-half inch. If a child or adult swallows a quantity of solid objects—for example, bits of glass, corn or vegetables having indigestible seed-coats, the pits of fruits, etc.—when may we expect the appearance of the foreign body at the anus? From some slight experience and much study, we may lay down the rule that, there being no diarrhea, the first of the foreign matter will appear in twenty-four hours, the last at the next day's passage.

The esophageal murmurs are commonly described as first and second, only one being present. A clearer and simpler way of stating the thing is that the sound made by liquids passing through the cardia varies from a sharp squirting to a low gurgle, according to the force of peristalsis and the degree of contraction of the cardia. The sound is of slight diagnostic value.

*Presented to the Section on Physiology and Dietetics, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

3. *The Stomach.*—Probably every one who has given much attention to this organ will agree that if we could know but one fact regarding it, we should choose to be informed as to its acidity. There is no longer the least doubt that the normal secretion is of hydrochloric acid, along with pepsin and rennin. A long list of series of experiments with various meals allows the general statement that, after an ordinary meal, there is a period of from one to two hours, according to the size and nature of the meal, before the capacity of the proteids is reached by the acid secretion. From this time on there should be a small excess of HCl, and, provided the excess is not sufficient to irritate the stomach, the exact proportion is not a matter of importance. While HCl is undoubtedly an antiseptic, it is not very markedly so in a proportion so small as not to irritate the mucosa, and the fermentation in achlorhydria is rather due to lack of digestion of proteids and to the usual concomitant failure of peristalsis than to direct lack of antiseptic. After a light meal, however, such as the test-breakfast, there should be found, after an hour's preliminary digestion, more than a trace of HCl, not because more is needed for that particular meal, but because the stimulus of food should call forth something like the normal quantity of HCl secretion. Just what this excess should be is a matter of controversy. Gastric juice contains about 20:10000 of HCl, and this may be taken as the maximum of free hydrochloric acidity which should be found in the chyme. Is it correct, following what might be termed the Boardman-Reed school, to call hyperchlorhydria every case in which the chyme after the test-meal contains more than about 10:10000 of free HCl? If so, we shall find hyperchlorhydria a comparatively common neurosis, and we shall find an excess of HCl in connection with quite a considerable organic acidity, in numerous instances. The opposite view, to which the writer subscribes, is that a case should not be called hyperchlorhydria unless there is at least the amount of free HCl found in normal undiluted gastric juice, or unless there is an excessive dilution of the food with gastric juice of considerable hydrochloric acidity and unless the HCl is clearly the cause of symptoms of irritation. According to this view, hyperchlorhydria can not coexist with any appreciable degree of organic acidity, except occasionally on account of the introduction of food already fermenting or very prone to fermentation. The difference of definition is not entirely a matter of terminology, as, according to the conception of the case, one might administer HCl, another alkalies, and both can not be right. The real question is whether, in these cases of gastric irritability, the HCl is the irritating factor or a conservative one. Löwenthal, quoted by Alois Pick, of Vienna, in a pamphlet on gastric hyperesthesia, introduced 250 c.c. of 3 to 10 per cent. solutions of HCl and lactic acid respectively, into the stomach, through a tube, and allowed the solutions to remain from one to several minutes. These solutions, varying from fifteen to fifty times the strength of normal gastric juice, produced no sense of burning or pain, although the stomachs were hyperesthetic to substances produced in the course of digestion. Hence, it seems conclusive that the HCl is not the irritating factor, unless organic fermentation can be excluded, and that we should not use the term "hyperchlorhydria" nor oppose the hyperchloric secretion, unless organic acidity is nearly absent and hydrochloric acidity surpasses the standard of gastric juice, i. e., 20:10000.

Text-books are surprisingly non-committal regarding the amounts of free or combined HCl, and of total acidity to be expected under normal conditions. Using dimethylamido-azobenzol as an indicator for free HCl, alizarin as an intermediate indicator and phenolphthalein for the total acidity, I should place the degrees of acidity, meaning the ratio of decinormal solution of monobasic alkali to the quantity of chyme used, about as follows: Total acidity, 50 to 100; combined, 20 to 30; free HCl, 20 to 50. Free HCl should be about half the total acidity.

When, a few years ago, Boas announced that the formation—not the presence or introduction—of lactic acid in the stomach was pathognomonic of carcinoma, most Americans accepted the statement as gospel truth. Some few of us were skeptical enough to exclaim: "How can lactic acid, which can be produced from almost every food except pure fats and oils, by any one of six or a dozen different bacteria that may be present in the stomach, be pathognomonic of cancer or of anything else?" But it required much tedious labor to disprove the assertion. Like every fallacy, this statement does contain a germ of truth. Lactic acid is the most conspicuous product of fermentation in the stomach. While practically always present in traces, the disease which most frequently and uniformly results in marked gastric fermentation is carcinoma and especially that of the pylorus, with secondary dilatation and stagnation of gastric contents. But there may be carcinoma without lactic-acid excess, or vice versa.

A very practical suggestion for the busy physician is whether stomach contents change materially after withdrawal, so that the results of examination would be vitiated by delay. From numerous experiments, comparing titration tests immediately after withdrawal and at the expiration of several days, I am able to state that, if cooled immediately to 40 F., very slight changes of any kind occur within two or three days, though there is a gradual absorption of free HCl by proteids, with corresponding increase of acid albumin and, possibly, of albumose.

While HCl fluctuates according to trivial exaltations or depressions of gastric function, pepsin and rennin are always present in gastric juice in sufficient quantity, except in the gravest gastric conditions, carcinoma, anadenia and achylia due to severe constitutional states, such as Addison's disease, according to a personal observation, and probably high grades of fever and the antemortem state. It is usually said that, if rennin is present, pepsin is also, and thus the simple experiment of curdling milk may be substituted for the more tedious one of digesting albumin. I have observed a case of carcinoma in which the rennin test was normal, but albumin was not digested, even after adding HCl. Ptyalin, by the way, is practically never lacking, according to 1000 experiments by Ewald, and I can add my mite in corroboration. The practical deduction is that ferments are very rarely indicated as aids to digestion. Certainly, they should not be given unless their lack has been actually demonstrated, and, in such exceptional instances, the chances are nine out of ten that the stomach and bowel are in no condition to act as digesting cavities, even with artificial aid, and that predigested foods should be given instead of ferments.

It was formerly believed that the stomach emptied into the intestine, all at once, several hours after a meal, but we have long known that the emptying takes place in waves, beginning within a few minutes after a meal and continuing at intervals of a few minutes throughout gastric digestion. The portions allowed to pass the pylorus are semi-liquid and quite completely digested, according to the standard of thoroughness of the stomach, which is not very high. Personally, I am inclined to believe that further observations will show that there is exceedingly little absorption through the glandular membrane of the stomach, and that the potassium-iodid test really marks the first peristaltic wave into the intestine, provided that the gelatin capsule is rapidly soluble. The salol test for gastric motility usually results positively three-quarters of an hour after taking the powder, and this, I have shown, is the case whether the powder is given immediately at the conclusion of a meal or at some other time. Some years ago I made a thorough study of this test, including not only personal observations, but the work of others, with the following conclusions: The test can not possibly represent an emptying of the stomach, though it may theoretically correspond in time to the average motility of this organ; the very conditions which are prone to accompany delayed motility, diminished hydrochloric acidity and catarrh, allow the absorption of salol from the stomach (Cornil); the test does not agree with the other more reliable clinical observations; no reliance can be placed on it unless in such extreme instances that the existence of stagnation is already evident. Ewald, to disprove these views, ligated the pylorus of dogs and found that absorption of salol did not take place. These experiments, however, are fallacious, because: 1, the animals were presumably healthy, there being neither diminution of HCl secretion nor mucous excess to favor the absorption of salol from the stomach; 2, the shock of such an operation would naturally prevent absorption, according to all surgical experience.

A very practical question regarding gastric peristalsis is as to its excitability by electricity. Experiments on this point, by Einhorn, Meltser and others, are somewhat contradictory. All, however, agree to a very practical extent. Contractions can be readily, though slowly, produced, if one or both poles are applied to the peritoneal coat of the stomach, and they either do not occur at all or only infrequently if one pole is within the stomach and the other on the skin. On account of clinical experience I abandoned this method seven or eight years ago. More recently, having a patient who insisted on its use, I connected a stomach-tube with a bubble manometer. which, although simple and not adapted to quantitative estimates, is very sensitive. After several séances, we were convinced that, while respiration affected the endogastric pressure considerably, the faradic current had not caused a single peristaltic wave, though a few had occurred during the séances. In vivisections, I have frequently been able to confirm the belief that gastric peristalsis, due to faradism, even with both poles on the serous coat, is tardy, slow and slight and by no means equal to that produced by mechanical irritation.

An ingenious but fallacious method of judging of absorption, etc., depends on quantitative examinations applied to chyme, after the introduction of known quantities of certain substances. For instance, to prove that soluble solids, but not water, are absorbed from the stomach, a sugar solution of known percentage is introduced. After an hour, the stomach is thoroughly emptied and the liquid quantitated. The invariable result is a diminution of percentage, after allowing for the additional amount of water introduced in thoroughly cleansing the stomach. But this diminution is inevitable from the fact that some sugar is lost by a passage through the pylorus, while water is added by secretion of gastric juice. For instance, in a case of hyperchlorhydria, I found 500 c.c. of chyme an hour after a test-meal amounting altogether to only 250 c.c. Similar, but less striking results are often noted. Huber's oil test, consisting in the estimation of oil remaining after an hour and intended to afford information as to gastric peristalsis, lacks this theoretical error, but it is extremely difficult to remove every particle of oil by lavage, nor is it possible to deduce information as to how the stomach will deal with ordinary food from observations as to how it responds to a stimulant of peristalsis, like oil.

INFANT-FEEDING.*

ALEXANDER McALISTER, M.D.

CAMDEN, N.J.

There is no more important subject in the domain of preventive medicine than that of infant-feeding. While the melancholy fact remains that a third of all infants born, largely because of improper nutrition, die before the completion of their third year, the abundance of literature on this subject constitutes no sufficient reason why it should not again and again be taken up. On the other hand, the infant mortuary records plead piteously that the subject be not laid aside as threadbare. It is not merely on a par with the most important subject in preventive medicine, but is itself the most weighty in this branch of the sanitary sciences. Not merely the life and well-being of the infant and child, but those of the adult and generations yet to be born are most vitally influenced by proper feeding of the infant. That real progress has been made in our understanding of the subject no one endeavors to say. That we are better able to cope with the needs of so great a problem than they of the former generation many are fondly hoping. Yet when the more or less completely theoretical is brushed aside and the practical weighed in the business balances, the progress made in life-saving appears alarmingly visionary. Our clear conception of the chemistry of human milk in all its minutiæ has failed to give us a synthetic breast milk capable of producing precisely the same physiological effects as the natural product; and it is essential that this fact be more generally recognized and made the basis of action.

Mother's milk for mother's baby affords human food for a human being, and will go farther to solve the vexing problem of a persistently high mortality among infants than all the chemical erudition in the world. A recent German writer has well said that the natural food of infants is not vegetable, but animal, and that proper digestion and nutrition depend more on the biology than on the chemistry of the food taken.

The purpose of this paper is to plead for a closer adherence to, and a stronger advocacy of, Nature's method of feeding on the part of our profession. Two forces are to be combated in this connection, if we would make genuine advances. The first is the present alarming disinclination on the part of mothers to breast-nurse their offspring, and the second is the clamor for commercial supremacy in the sale of artificial foods. These are mutually independent, each taking advantage of the other. Young married women wish no offspring, and finding themselves mothers, they shirk the vitally important duty of committing themselves to the highest interest of the child. It may be her false modesty, the pressure of social functions, the desire to return to her former employment in the office, storeroom or mill, or her wish to place the immediate care of the child into the hands of a skilled nurse, that prompts the mother in this course. In this she is abundantly encouraged by the multiplicity of so-called infant foods and the manner in which they are advertised to the public. Her false logic that whereas only the mother can care for a breast-nursed infant, anybody can attend to the bottle-fed, is sustained by the sight of scores of fat babies' photographs used to exploit the merits of an artificial food. Since fat babies are by no means of necessity healthy ones or such as possess a normal measure of resistance to disease, this is also a real force to be combated. Breast-nursed infants may or may not be fat, but the chances are that they are robust and fleshy, which is better. They are not exposed, as are hand-fed infants, to a great many common sources of infection; and when exposed they have greater powers of resistance. Cow's milk, which of necessity enters more or less into the composition of the food of all hand-fed infants, is peculiarly adapted to absorb all sorts of impurities and convey infection. From the time it leaves the udder of the cow until it reaches the nursing-bottle it unavoidably meets sources of contamination and naturally invites infection wherein exposed. When we consider how manifestly unhygienic are the surroundings of the average dairy stable, and how perfect a culture-medium milk is to some pathogenic bacteria, we may well marvel that the mortality of bottle-fed children is not vastly higher. To control this prolific source of infection previous sterilization or pasteurization is universally recommended, but what proportion of hand-fed children receive such milk? The stoic truth of the matter is that both the necessary equipment to sterilize the milk properly, and the patience and skill required to persist in such sterilization days and weeks and months, and it may be years, are not found in the average home, and thrice blessed is that family in which they are not demanded. Nor is the problem well solved when the absolute sterilization is assured, for are we not ready to admit that sterile and sterilized milk are not equally valuable food? Are not pasteurizing milk-plants yielding their own measure of disappointment?

---

*Presented in a Symposium on Infant-Feeding and Diseases of the Digestive Tract, to the Section on Diseases of Children, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

It may be taken for granted that every man, even in his infancy, is a law unto himself, and likewise every mother. Diversities of individual circumstances and idiosyncrasies make it needful sometimes to have early recourse to hand feeding, but the rule should be that while the mother's breast secretes milk at all, the child shall have all the benefits to be derived from it. Koplik recently showed that the advantages to the infant of even one breast-nursing in the course of twenty-four hours are too great to be lightly regarded. Infants having at least this advantage thrive better and grow faster than when wholly hand-fed. In such instances there is increased difficulty to determine the proper quantity of cow's milk to supplement the nourishment obtained from the mother, but this is generally quite easily overcome and never outweighs the advantages to the infant of mixed feeding. Part breast is superior to all hand feeding, and should be universally so recognized. If for any reason the mother's breast is wholly valuless let the cow's take its place, but before this change is made the mother should receive proper treatment to stimulate, if possible, adequate flow of milk. It is reasonable to suppose that if the medical attention which early weaning necessitates on the part of the infant were bestowed on the mother a fair proportion would be enabled to suckle their offspring and many children would be saved from early graves. It is well to remember, when searching for an efficient galactagogue, that nutritious food is superior to drugs, and that the "queen of the dairies," who broke every record for a large yield of rich milk, took in addition to her allotment of provender the milk of other cows.

Granted that every proper effort to make the mother profitable to her infant has resulted in failure, feeding with cow's milk is by common consent the proper recourse, but the problem is by no means rendered easier by the change. It is now vastly more complicated and difficult, and should be so regarded by the physician and mother. Cow's differs materially from mother's milk, and as ordinarily procurable is never sterile. Modification is necessary, but cleanliness is imperative. Cleanliness in the dairy, the milk, the bottle, the attachments, the infant—everywhere—counts for vastly more than *does copying the composition of average human milk*; yet both enter into the vexing problem of hand-feeding. The milk laboratory commends itself on the score of cleanliness and uniformity of composition of the milk which it insures, but in a large majority of instances home modification is still the only recourse at hand.

The writer's experience leads him to place special emphasis on the careful selection of a product of milk; that which is properly collected, cooled and at once tightly bottled, when delivered within a reasonable time and kept in close proximity to ice until needed, is always to be preferred. Such milk may be expected to yield even better results than laboratory milk; under ordinary circumstances it need not be subjected to the usual process of sterilization. So much for the cleanliness of the milk itself, and in conclusion a word about home modification. The excess of proteids is best reduced with water—that which has been previously boiled; and for an infant under 2 months old, pure milk, diluted with equal parts of water, will generally prove a proper food. For older infants, if the character of the stools or the progress in growth indicates that a change may prove beneficial, a smaller quantity of water or water with one of the artificial foods should be used in modifying the cow's milk. It is here that the infant foods of commerce are properly employed. They reduce the native proteids, render more easily digested the relatively tough and dense casein from cow's milk and serve as ballast. One of the few brands which have been employed by the profession for many years can generally be selected—that which seems best to suit the needs of the individual case—with a fair degree of assurance that satisfactory results will follow.

285 Federal Street.

EXACT INFANT-FEEDING: ACCIDENTS AND INCIDENTS.*

W. P. NORTHRUP, M.D.

Professor of Pediatrics, Bellevue Hospital Medical College; Visiting Physician at the Foundling, Presbyterian, and Willard Parker Hospitals.

NEW YORK CITY.

The object of this paper is to call attention to the accidents which may arise from the very exactness of the methods employed. I do not mean to say the accidents are inherent in the methods; I am going to call your attention to certain responsibilities on the part of the physician. Accidents may arise in mechanical ways; they may arise from faults of a higher order. Let us assume that we are agreed upon the following:

---

*Presented in a Symposium on Infant-Feeding and Diseases of the Digestive Tract, to the Section on Diseases of Children, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

1. That cow's milk is the only variety of milk to be considered in substitute feeding. 2. That dairy cleanliness is necessary. 3. That the modification of milk according to some definite formula is demanded. 4. That it is desirable to have the milk modified in a laboratory for purposes of cleanliness and exactness.

The discussion of the respective values of gravity and centrifugated cream does not enter into consideration here; a laboratory furnishes what is ordered, as does a drug-store. Some one has said: "You may order red ink in the milk and it will be put in." I am asking you to assume no more than I myself fully believe, namely, that dairy cleanliness, percentage feeding and properly conducted, well-equipped milk-laboratories constitute an essential advance in infant-feeding. If these points are allowed, we come to the subject of this paper, viz., the accidents of exact feeding, the abuse of exact methods, if you please. Modified, clean milk is one thing; the modification of milk is another. The modifier of the milk is the physician. I am going to ask the physician to take to heart the fact that he assumes a distinct responsibility when he consigns a child to a fixed formula. The other thing—the normal growing child is not the same infant in his physiologic demands more than a few weeks at a time. Upon the physician falls a certain responsibility; when he writes and records a prescription he assumes this; when he consigns an infant to that prescription the responsibility continues until he changes the prescription.

The following case will show what may happen: A female infant born at term may be said to have started life fairly; the parents were apparently healthy, even robust; the other children in the family were healthy. When three days old it was put upon modified milk from the Walker-Gordon Milk Laboratory; this was the prescription: Fats, 2 per cent.; sugar, 4.5 per cent.; proteids, .75 per cent.; lime water, 5 per cent.; heated to 167 F. Two ounces each feeding. By the twenty-seventh day the feedings had been increased gradually to fats, 3 per cent.; sugar, 6 per cent.; proteids, 1 per cent., etc.; a prescription which would be considered satisfactory for the age. Soon after this the patient went to the country, the feedings being sent to it by express daily. For 4½ months there was no supervision of the child, no change in the proportion of its food-ingredients. At the end of the summer, there was one small advance in the proportions—fats, 3.25 per cent; sugar, 6 per cent; proteids, 1.75 per cent.—and the child was lost sight of for 3¾ months. The infant had now arrived at nine months of age. It was getting its first teeth at this late date, without trouble; some slight swelling of the gums was noted; there was no bleeding and no discoloration. Teething was, of course, late, but apart from this there was nothing to call the attention of an unprofessional person to the child's condition, not even of an anxious and watchful mother. Indeed, the mother was quite confident that it was doing well—was it not fat?

One week after the appearance of the first teeth the unexpected happened. While wheeling the baby in the park the nurse observed one eye was unduly prominent, and, looking again, it was black and blue; she started for home, not a long distance away, and, to her astonishment, on her arrival there, found the other eye in a similar condition, though not so markedly. The family physician, on his arrival, found the appearances described above, plus marked tenderness of the ankles and knees; both were slightly swollen and painful, the ankles more sensitive than the knees. He also noted the fact that she used the legs less than she should normally. Some blood was passed from the bowels; blood was also found in the urine. The case was obviously scurvy. General treatment for anemia, with marked increase of the ingredients of the milk soon caused an improvement in the symptoms and a subsidence of pain, tenderness, swelling, etc. Note the fact that the improvement took place on milk still heated to 167 F., and containing the same amount of lime-water as before. Increased proportions and general treatment was all the change made. Neither orange-juice nor beef-blood was given.

The evidence of scurvy quickly disappeared under the influences of corrected regimen, but the case was not then well. It was a pronounced case of rickets. No clinic ever was favored with a case for demonstration of better showing qualities than was this child. For several months it could only sit upright between pillows on the floor. At the end of two years it was able to stand beside a chair, and was thought to have done wonderful feats when at last it could take those three or four little steps from one encouraging friend to another.

This case is here considered scurvy plus rickets, one disease of malnutrition superimposed upon another; the cause persistent and long-continued feeding upon milk furnishing insufficient nutrition; scurvy quickly disappeared under corrected regimen, the pronounced evidence of rickets after months of sufficient food, and after time enough for nature to strike its nutritional balance.

The child of the careless and ignorant may acquire rickets from improper food-proportions; but from the table of its elders it will obtain unhygienic apple cores, which will, at least, save him from scurvy.

To fix the feedings of an infant of one month and then lose sight of it for several months is not discharging our full responsibility. I am not forgetting that oftener it is the fault of the parents rather than of the doctor, as it assuredly was in the above case; they, however, are acting without knowledge and are less culpable. The busy general practitioner may forget. I am only in the fashion if I blame everything upon the doctor. It is enough if, in any way, I succeed in putting "a word to the wise." My experience leads me to think many babies are at this moment behind their age in the proportions they are taking in their laboratory feedings. I have recently heard the expression: "The baby is on 4—7—2; now (with a sigh of satisfaction) he can go a year." This voices the sentiment of many. There is a better method, however, and that is to advance the proportions gradually to a "full" milk; that is, to undiluted milk, fed clean and raw. This may often be accomplished at 8 months. My greatest ambition is to graduate to a full milk at 8 to 10 months.

In connection with this history I am reminded of a spontaneous expression of one of my neighbors in New York. "Yes, that case died; and I gave it Walker-Gordon milk, too." This expression better expresses the attitude of many of the profession than any other I have happened upon recently. He might have said with equal propriety, "I gave the child drugs, and it died just the same." The doctor avers he gave it "everything known" for summer complaint, including all the proprietary pulverized milks, and at last Walker-Gordon milk.

Gentlemen, I have purposely narrowed my subject. When I speak of accidents of feeding, I am not thinking of the unfortunate poor, of those in unhygienic surroundings, fed on grocery [illegible] those [illegible] circumstances place at the dis[illegible] f [illegible] ser reasonable requirements. I have pointed out some of the accidents. I shall be required to build if I have pulled down.

MEMORANDUM OF NEW FEEDINGS.

1. Begin all feedings of new-born and sick infants with very low percentages; assuming that a normal child has a certain scheduled formula, that same child should when sick have a feeding appropriate for a younger child. Reduce the strength of food for all sick children. I am inclined to begin the feedings of new-born and sick infants on fats, 2 per cent.; sugar, 5 per cent.; proteids. 0.75 per cent.; lime-water, 10 per cent., heated to 155-167F.; eight to ten feedings in 24 hours, of 1½ to 2 ounces, according to age and condition.

2. Increase the strength of feedings just as fast as the child can take it. The digestion of a growing, healthy child, as tested by the passages, is the important guide. When the passages become pasty—homogeneous—all one color, smooth like lard, canary-colored, the digestion is such as to warrant increasing the strength. Feedings of very young and convalescent infants can often be increased every two or three days to advantage. Such should be very slight increases and dependent upon the testimony of the diaper. In case of sick infants, the prescription should be changed less often or changed less abruptly.

An infant is not the same for more than about two weeks at a time. A thriving infant can to its advantage be seen every two weeks, the feedings readjusted to its growth. The feedings, in short, should always be made to fit. If the infant changes so much, it is not the same infant. Well, the feedings must fit, hence the function of the doctor and the use of modified milk.

3. I suggest the following memoranda to serve as landmarks in substitute feeding for normal infants, from birth to eight months of life:

1. FIRST PRESCRIPTION.

Fats	2 per cent.
Sugar	5 per cent.
Proteids	.75 per cent.
Lime-water	10 per cent.

Amount in each feeding, two ounces; number of feedings, 10; heated to 167 F.

2. LOW AVERAGE BREAST-MILK.

Fats	3 per cent.
Sugar	6 per cent.
Proteids	1 per cent.
Lime-water	5 per cent.

Amount in each feeding, 2 to 4 ounces; number of feedings, 8; heated to 155 F.

3. HIGH AVERAGE BREAST-MILK.

Fats	4 per cent.
Sugars	7 per cent.
Proteids	2 per cent.
Lime-water	5 per cent.

Amount in each feeding, 4 to 6 ounces; number of feedings, 6; heated to 155 F.

4. At 6 months the figures of memorandum arrange themselves in multiples of 3 thus: 3—6—6, 6. Intervals, three hours. Number of feedings, six; amount in each, 6 oz.; age in months, six; nuheated—not Pasteurized—especially in winter season.

5. At 8 months, frequently, "full" milk, clean, may be fed "raw."

6. In prescribing, sick and feeble infants may be considered physiologically younger than their accredited age.

7. The fats, sugars and proteids should be advanced together, usually, by fractions of a hundred and at frequent intervals. Keep the prescriptions level or balanced, so to speak.

Finally, to summarize:

1. Clean cow's milk, modified to some definite formula, is demanded.
2. A laboratory for modification is desirable; it secures greater exactness and cleanliness.
3. The physician should frequently revise his formula; frequent small percentages of increase are to be advised.
4. Accidents may arise from consigning an infant for several months to insufficient food ingredients. A baby is not the same baby for many weeks at a time; its growth and physiologic demands change so much.

DISCUSSION ON PAPERS OF DRS. M'ALISTER AND NORTHRUP.

[This discussion was opened by Dr. Henry Dwight Chapin. but we refer our readers to his able article on "Substitute Infant-Feeding," in The Journal of July 14, in which his remarks are incorporated.—Ed.]

Dr. Victor C. Vaughan, Ann Arbor, Mich.—I find myself in a predicament this morning, for I am down for three talks at the same hour, all in different places. I have very little to say here, and I must condense it as much as possible. I am very sorry that I have not heard all the paper just presented. I agree thoroughly with Dr. Chapin regarding the partial failure of sterilized milk. It has not done everything that we expected it would do. I also agree with Dr. Chapin very fully in the belief that the fine modifications of milk are unnecessary and, I might say, are unjustifiable. I do not believe that they are especially beneficial. The animal body is so made that it can take care of a little excess of any one of the food stuffs. I am sure that the sterilization of milk, as ordinarily carried out, and even the pasteurization, is not desirable. If we can obtain perfectly fresh milk from the cow, with certain commonsense modifications we have the best food for the baby. The chief proteid in milk is a nucleo-albumin, and there is no question that it is changed by high temperature.

I have spent considerable time in ascertaining the exact temperature at which this change takes place, and it seems to be fairly sharp. A milk heated to 158 F. shows but little change; a milk heated to 160 F. shows quite a marked change. If the milk be heated long enough, and two or three times, it can be fairly well sterilized by heating it not higher than 158 F. I still believe that the high-death-rate from the summer diarrheas which continues notwithstanding the sterilization of milk, is due to failures in sterilization. The colon germ, I suppose, is the most frequent bad germ in milk, being almost universally present in market milk. This germ varies exceedingly in virulence. We can take a colon germ of moderate virulence, and we can increase that virulence so that .05 c.c. will kill a guinea-pig of a given weight in two or three hours. The colon bacilli, and probably other bacilli, grow rapidly in milk under certain conditions, and there is no amount of sterilization known that will destroy the toxin of the colon bacillus. If you will grow some of these bacilli on an agar culture, and allow them to grow for two or three weeks, and then scrape off the surface growth, you can heat that germ to 160 C., or 356 F. in a sealed tube with water, and there will not be the slightest effect produced on the toxicity of the poison. When you think that you can get a colon bacillus that furnishes a poison, one-fourth of a milligramme of which—1/270 of a grain—will kill a guinea-pig, you can have some idea of the powerful toxin that this germ produces, and which is not destroyed by any method of milk sterilization that we can resort to. We must, therefore, content ourselves with taking care of the milk and preventing its contamination. Most of the laity, and some physicians, think that any milk is all right if it is only properly sterilized. From what I have said you can readily see that no amount of sterilization can make milk containing this germ, sterile. The colon germ has an envelope varying greatly in its resisting power according to the virulence of the germ. The toxin is contained within this envelope. If you will take some of the colon germs, grow them, as I have indicated, scratch off the germ cells and put them in artificial gastric juice, and leave them there, it will completely dissolve the cell wall, and leave undigested the substance which I told you will kill guinea-pigs in a dose of 1/270 of a grain. No amount of heat up to 160 C. or 356 F. has been found to have the slightest effect on the toxicity of this poison. I am sure that a milk which is already a good culture of colon bacillus can not be made safe for a child by any known method. We can kill the germ, but we can not get rid of the poison. This shows clearly one of the limitations of sterilization of milk.

Again, sterilization must be left more or less to the intelligence of the mother or nurse, and we all know of the resulting accidents. I was once called to a child suffering from diarrhea, and on inquiry I found that the nurse had a bottle of milk that had been properly sterilized, but I saw her pour the milk into a glass which she had previously roughly wiped out with her apron! I know of a case of poisoning that occurred from a growth of the colon germ in this way. The milk was received at the house at a certain hour each morning, but one morning, instead of being put on the ice directly, it stood for three hours at the summer temperature before being sterilized. That milk poisoned the child.

DR. WILLIAM L. STOWELL, New York City—The subject of infant feeding can not be presented in five minutes, but this time may enable one to call attention to a few important points. Percentage feeding is certainly ideal, but sometimes it is not so in its results. The point that should be made, I think, is that we do not sufficiently distinguish between the therapeutic effect of giving a child proteid and the nutritional value. When a child is very young, or has indigestion, we know that it can not readily digest the casein of cow's milk. We forget that after the child has recovered from the disturbance of digestion we must attend to the nutrition. The result is that the child is often kept for a long time on food having improper nutrient qualities. In order that a child may thrive and increase properly in weight and strength, and so not be subject to rickets or scurvy, the proteids should be increased just as early and as rapidly as possible. I have believed this, in a general way, for a long time. In hospital service I have insisted upon having the children placed as early as possible upon the largest possible percentage of proteids. I have often put them upon whole milk when only six months old. The effect of this practice was soon noticed by all the nurses of the hospital. I have obtained from the house physician a list of the children placed upon whole milk. Most of them being foundlings are poorly nourished when received. Two extreme cases will illustrate the matter. A child of 1 year had been given everything, and was suffering from marasmus. It was given milk represented by the formula: fat 3, sugar 6, and proteid 1. It continued to fail at first, but in one week after being put on whole milk it began to thrive. The other case was that of a marantic child of three months that gained thirteen ounces a week for two weeks on whole milk. A child of this age should not be theoretically placed on whole milk at all, but if children have a reasonable digestive capacity they can take a reasonable percentage of proteids, and should receive this amount. A moderate excess would be burned up. A child will not grow strong on sugars and fats if the proteids are kept low. I have had a case of scurvy develop in a family in which I had had the direction of the modification of the milk at first. The child had then gone away and had been kept for a number of months on milk intended for it at a much earlier age. I would, therefore, insist upon the fact that children can, and will, digest a large percentage of casein unless absolutely sick. I am convinced that the milk given should be whole milk whenever possible. No diluent is needed for a child above six months old except 5 per cent. lime-water.

DR. A. JACOBI—I understand there is a general session going on now, and that we should adjourn, so I will speak very briefly. If any one of us has come here under the impression that he could positively learn how to feed children, he must have learned by this time that he was mistaken, for every one of the speakers here has told you positively what you must do, and the advice was different in every case. Now, I advise you to use your own brains; it is wonderful how handy are brains in the practice of medicine! One physician tells you the milk must be diluted; another one says the milk must be given absolutely pure. Every one knows that he was correct, and a large number of babies know that he was not. I can not decide that question; I only know that what I have been teaching the last forty years has been nearly right. I find that people are coming around generally now—even those who most objected to it—to dilutions with cereals, such as Dr. Chapin has spoken of. I think it is the best plan, and I do know that pure milk will not be digested by the average baby—by that I mean nine babies out of ten. I do know that when you sterilize wholesale, no matter whether you call it Walker-Gordon milk or not—and separate the milk into its constituent parts, you can never make proper milk of it again. The same remark applies to all centrifugated milk. Again, though the percentages are finely spun out from day to day, and change perhaps from week to week, as Dr. Northrup has said, you are still not sure whether it might not have been better to change that milk sooner. You will find that mother's milk varies not only from day to day, but from morning to evening. There must be some mistake in the theory that milk must be given just in those percentages that the physician believes he has found out. Fortunately Dr. Vaughan has told you that Nature is a little more generous than doctors and their theories. She allows a good deal of latitude. If it were so very dangerous to have half an ounce more or less, and a little bit of sugar or water more or less, there would not be a child in Creation living. The taking, by a baby, of a little more milk at one time than at another is not a sentence of death. The normal baby will pass out a good deal of what it takes even from mother's milk. In the diapers of a baby you find undigested food, even in the very best-looking feces. This is true of all babies; the stools contain 5 or 10 per cent. of fat. A mother gives a baby too much fat, and you say she should be rebuked for it. Now, I appreciate the good that has been done with boiling and pasteurizing and sterilizing, and I have been teaching the advantages of boiling milk for forty or more years, but I do wish to say that we are overdoing our theories. Be sure that you have good milk, and that you mix it in the proportion that has been found experimentally to do some good, and be satisfied with the result. I repeat again, milk that has been separated into its constituent parts can never be restored to its former state by mixing the separated portions together again.

DR. A. C. COTTTON, being called upon, said: How can I be expected to add anything to the succinct statements to which we have just listened, except to add my hearty indorsement?

DR. J. P. CROZER GRIFFITH, Philadelphia, Pa.—I do not wish to take up the time of the Section, but I disagree with many of the statements that have been made. I shall speak only on one point. Regarding the relation of milk of a certain character to scurvy I wish to say that, from the statistics collected a few years ago, I am sure that the sterilization of milk is perfectly capable of producing infantile scurvy, at the same time I am a thorough believer in sterilized milk under certain circumstances. This is because I believe that the sterilization of milk often is the lesser evil. We must above all, as Dr. Jacobi has said, use our brains, and adapt well-known principles to the individual case. I can recall having seen four cases of infantile scurvy in the past few months in children fed on unsterilized laboratory milk. I am a firm believer in laboratory milk, and there was certainly something wrong with the milk in these particular instances. I do not well understand what produces scurvy, and I do not understand the chemistry of milk very well.

DR. HENRY KOPLIK, New York City—I believe, with Dr. Jacobi, that we should try to feed the child and not try to work out mathematical formulæ to which the child must be made to conform. As far as healthy children are concerned, we must make a very close distinction between them and children who are not quite well. If the milk is roughly diluted for the perfectly healthy child by any of the methods known, the child will probaby digest the milk and thrive. Dr. Vaughan has called attention to the fact that a child may have good food to begin with, but before it has finished nursing its food may have become contaminated in such a way that the child immediately becomes an invalid. This is apt to occur from lack of cleanliness on the part of the nurse or mother. The milk may have been very clear, and have been carefully pasteurized or sterilized, yet if the careless mother or nurse handle this milk, perhaps just after diapering the baby, the child is liable to develop a severe gastro-enteritis. I have been [illegible] to instill the doctrine that [illegible] mother must be ta[illegible] and that the milk must be clean at the beginning, not only, but that it must be kept so. If this is done, a great many of the dangers threatening the infant will be averted.

Regarding sterilization, let me say that this problem is by no means solved. Some pediatrists insist upon raw milk being used, others on sterilization, and others still on pasteurized milk. This shows that the problem is far from being settled. Dr. Vaughan has told you that it is impossible to sterilize milk thoroughly, and this is true, but you can keep milk wholesome until the last bottle is used. The point is that the milk must be pure from the time it leaves the cow until it is swallowed by the baby. It is simply an impossibility to get a milk that is absolutely germ-free. The milkers are often just as uncleanly as the cow from which the milk is obtained.

I find that one of the principal things that has stood the test of time, and which was first brought forward prominently by Professor Jacobi, is the dilution of the milk in various ways. It is diluted, 1. to reduce the percentages; and 2, to break up the curd. Dr. Jacobi advises cereals, but personally I do not use cereals, preferring simple water as a diluent. If, however, this mode of dilution does not agree with the individual baby, I seek for something else that will agree with it. I then use gruel, or perhaps dextrinized gruel. It is surprising to see how some of these atrophic babies who will not do well on any ordinary modification of milk will thrive on some malted preparation of milk, or on milk diluted with some of the gruels. We must not, therefore, try to make a test-tube of the baby.

Dr. William P. Northrup—It has been said that we all disagree. I think it is a very significant fact that we do agree upon one thing at least to-day, and that is the necessity of starting with an excellent quality of good clean milk. That is a monument of the advance in infant feeding which is most conspicuous. I was very much pleased with what Dr. Vaughan said about starting with a clean milk and keeping it clean. If a few bacteria get in they do no harm unless they grow and multiply, and leave behind a product which changes the quality of the milk. A few colon bacilli in milk kept at 40 degrees will not multiply or do harm. Several of the speakers have referred to the fine points I have drawn about percentages. I am not a stickler on such fine points. The kinds of mothers that I have to deal with are a very capricious lot, who will go to receptions and come home very tired and nurse their babies at a time when the milk contains a very large percentage of proteid. Nature may be very elastic, but I have seen babies very sick under these circumstances. I have learned to-day of a new mixture—so strongly emphasized by Dr. Jacobi—a mixture of milk and brains. This is like the great painter who mixed his colors "with brains." Dr. Jacobi has had the start of us in this matter of mixing brains with milk for forty years or more.

THE CREDULITY OF THE PEOPLE AS IT PERTAINS TO MEDICINE AND RELIGION.*

BY T. B. GREENLEY, M.D.

MEADOWLAWN, KY.

It would seem, from our every-day reading and observation, that the faith or credulity of the people is greatly on the increase. And this faith in the virtues of medicine and so-called doctors, is only equalled, or excelled, by religious instincts. If a new doctrine, either in medicine or religion, is promulgated, no difference how absurd it may be in the estimation of persons of common sense, there will soon be many believers or followers to embrace it.

By way of illustration we will allude to a few instances of this fallacious credulity, first as it relates to medicine. We see every day in the secular newspapers advertisements of wonderful curative remedies which have relieved patients after the treatment of the best doctors has failed to cure, and such published statements are calculated to excite the minds of the credulous to believe the statements, and if unwell, to try the remedies possessing such wonderful virtues. Then, if the article obtained contains any sedative like morphin, cocain or alcohol, which many preparations thus advertised do, the patient thinks, for a while, that it is doing much good, but soon finds it necessary to increase the dose, or it has but little effect. No doubt many habitués of narcotics, or drunkards, have resulted from this source. Many of these secret or so-called remedies for certain diseases, are composed of simple medicines, mixed with narcotics or alcohol in order to produce pleasant effects while under their influence; and some contain, perhaps, medicines which, if long continued, will produce a disease similar to the one they are recommended to cure.

Some advertisers of medical preparations head their notices with large letters, accompanied with pictures of skeletons, or death as a warrior with sword ready to destroy life; again, we now and then see the picture of a terrible serpent ready to coil around or perhaps swallow one, then again, we see a heading of a man ready to swing from the gallows with the rope around his neck, but the news of reprieve comes just in time to save him. This represents a condition of approaching death, when a great medical "discovery" is applied, and the patient is saved, after all doctors have given him up to die.

These terrible looking pictures are intended to alarm and impress people with the necessity of taking the medicine recommended in order to save their lives, etc.

A more pleasant aspect is in the fine photographs of persons said to have been restored to perfect health from death's door, and much better looking than formerly, the medicine having a beautifying effect, as well as restoring health.

You might ask: how can a patient, after reading accounts of such wonderful cures of diseases, which he imagines are similar to his own trouble, resist the temptation to try some of the remedy in his own case? The answer might be, that it is natural for a sick man to want medicine, especially if he sees attached to the advertisement the name of his pastor or some particular friend who claims it has cured him, no difference whether his is the same character of disease or not. This wonderful credulity is also manifested in the belief that the sick can be cured by "Christian Scientists," but this sect has more credulity than the patients. They deny the existence of pain or suffering on the part of the patients, and endeavor to induce them to believe their trouble is all imagination; that there can be no physical suffering; as no such thing as matter exists, everybody being immortal only. The "Christian Scientists" possess more credulity in the virtue of their plan of treatment, if possible, than our good friends, the homeopaths, do in the infinitesimal doses of their various preparations. I allude more particularly to their inert ingredients, such as chalk, silex, charcoal, etc.

In speaking of homeopathists, I allude to those who hold to the high-potency plan of treatment, but fortunately they seem to be somewhat scarce at present. Prof. Hale, one of their leading men, says there is scarcely one in a hundred so-called homeopathists holds to the true Hahnemannian theory. There is but little doubt that a large majority of those claiming to belong to that sect practice, mainly, regular medicine.

Then come our new friends, the osteopaths, who claim to cure all troubles by bone rubbing. This is more sensible than the "Christian Science" treatment, as it is based on the existence of matter. It might be asked how, if educated people like those just alluded to possess so much credulity as spoken of, can we blame the common people for believing what they hear of and see published in almost any paper?

---

*Presented to the Section on Materia Medica, Pharmacy and Therapeutics, at the Fiftieth Annual Meeting of the American Medical Association, held at Columbus, Ohio, June 6-9, 1899.

There is one character of advertising, the consideration of which should not escape our attention. I allude to those so-called remedies for female troubles, such as amenorrhea, etc. In our estimation they are the most pernicious, and attended with more danger, both to morals and health, if not life, than all others. Yet we see them almost every day in our secular papers, and unfortunately lately I have noticed one of the kind in a medical journal. In the latter it was particularly charged not to give the medicine to a pregnant patient, as it would produce abortion, and this warning was in quite large letters.

The most popular remedies for amenorrhea, published in the secular papers, are under the titles of pansy, pennyroyal, etc., but of course, contain other ingredients. They are guaranteed to afford certain relief. The remedies are very carefully put up, sealed and of course secret. The precautions accompanying these advertisements are of such a character as to intimate their nature to any parties who wish to produce abortion.

In speaking of different preparations of medicines, I do not wish it understood that I am alluding to any but secret remedies. I frequently use proprietary medicines when I know their composition by the formula. No doubt some of the patent medicines are of value, but physicians do not like to, and hardly ever, use them without knowing their composition. If the formulæ of all patent medicines were given on the packages, I believe it would be as well for the proprietors as at present. If they were thus labelled and contained ingredients adapted to the disease under treatment, we would not hesitate to prescribe them, as it is a rule with the regular profession to use any remedy by which we can accomplish good, but, as before remarked, we do not like to give something of which we know nothing. Therefore, it has long been my opinion that the proprietors of all patent medicines, if they are of value in the treatment of disease, would be as well off in the disposition of their remedies, if a law was enacted compelling them to place a formula of their preparations on all their packages. The doctors would not then refuse to use them and the people would know what they were taking, and would not be compelled to exercise their credulity in the dark.

As to credulity in its respect to religious beliefs, we have already spoken of the sect called "Christian Scienists," which partakes of both medicine and religion. It seems to be a fact, to the ordinary observer, that no difference what dogma in religion or medicine may be gotten up, it will soon have adherents or followers. As examples we have Mohammed, who claimed to be an inspired prophet of the Creator, and although at first he had hard work to obtain many followers, he fought his way and finally became the idol of his people. Then, in our time, we have the followers of Joseph Smith, and the Latter Day Saints, and more recently, Schlatter, claiming to be the second Christ.

When we take a common-sense view of the various aspects of credulity, we are almost forced to the conclusion that in many instances the parties thus affected are bordering closely on a state of insanity.

In the event of commission of crime, if the plea of insanity was made by the defense, many of our courts of justice would, instead of conviction, send them to the asylum.

The question now arises, what can be done to ameliorate or lessen this wide-spread credulity? This problem, perhaps, will have to be relegated to the distant future for a proper solution.

To borrow Folly's cap and bells,
  Though Wisdom oft descends,
Yet Folly to her cost doth find
  That Wisdom never lends.
That Wisdom hath oft played the fool,
  Is seen in every age;
But here the bargain ends, for ne'er
  Hath Folly played the sage.

THE MAMMARY AND THE PAROTID GLANDS.*

JOHN B. SHOBER, M.D.

PHILADELPHIA.

I deeply appreciate the honor you have conferred upon me by your invitation to take part in this symposium. I have been asked to say a few words in regard to the therapeutic value of the mammary and the parotid glands in certain morbid conditions of the female pelvic organs. Upon the receipt of the invitation, my first impulse was to decline, because, although my clinical experience has greatly increased since the publication of my last paper on this subject, I felt that I had nothing new to say at this time. Upon further reflection, however, I decided to embrace the opportunity in order to point out and emphasize how these agents should not be used. I have always tried to be very clear in my statements as to the precise indications which in my experience call for their use, and yet I find that physicians all over the country are employing them for every conceivable malady of the female accompanied by dysmenorrhea and hemorrhage. An article appeared in a recent number of the *Boston Medical and Surgical Journal,* in which the writer stated that he had used the mammary gland in a case of adenocarcinoma of the uterus, and, although he mentioned that it was used before the true nature of the case was discovered, and with the idea of controlling hemorrhage, yet the article has been abstracted in a number of journals in a manner which makes it appear that I have advocated the use of this agent in cases of adenocarcinoma and that in this instance it had proved of no avail. It is only another example of the harm that is being done by the careless abstraction which is now so common. The point of the article above referred to was that the menorrhagia and metrorrhagia were partially controlled by the agent, in spite of the malignant nature of the disease—as soon as the diagnosis of the case was made operation was promptly and successfully performed.

The Mammary Gland.—I employ the mammary gland in the form of a tablet which is made of the desiccated gland of the sheep. Each tablet represent 20 grains of the fresh gland. The dose is from 3 to 6 tablets daily. I find that while it has no unpleasant systemic effects, it seems to have a very positive action on the uterus, causing contraction of the uterine muscle, in this manner diminishing the blood-supply to the body of the organ and thus controlling bleeding. Its action therefore is very similar to that of ergot and in my experience is far more reliable and surer in its action than ergot and can be used over much longer periods of time without causing unpleasant symptoms. In uterine fibroids, I have used it with much satisfaction for long periods of time, in cases which had been characterized by an excessive and weakening menorrhagia and metrorrhagia. The bleeding can be brought under control in a few weeks and if the treatment is persisted in, the mentrual periods become regular and normal and unaccompanied by clots and pain. The health of the patient improves commensurately with the improvement of the anemia, resulting in increase in body weight. The tumors themselves are inhibited in their growth and development and diminish in size up to a certain point. Tumors in which the nodules can not at first be distinguished will in a few weeks or months so shrink and alter that the several nodules which compose them can be readily differentiated and the whole mass becomes much more freely movable in the abdomino-pelvic cavity. Such being the case it is clear that we have at our command an agent by which we are able to place many of these patients in a far more favorable condition for operation than has been possible by any means at our command in the past and it may be that the constant use of the mammary gland by these patients will indefinitely postpone the necessity for operation in many instances. So long as we are able to prevent the further growth of these tumors and keep the menstrual periods normal and no degenerative or inflammatory changes take place in the tumor or the adnexa, we are not, in my opinion, justified in submitting these cases to a major operation. When, however, we have reason to believe that serious degenerative or inflammatory changes have taken place or when after a reasonable trial serious pressure-symptoms can not be brought under control, operation should not be delayed. In addition to the above class of fibroids I have used the mammary gland in many cases of subinvolution of the uterus from any cause unassociated with malignancy or structural changes, with marked success —many cases in which the uterine canal has measured three inches or over have come down a quarter or half an inch in 5 or 6 weeks. The leucorrhea and irregular bleedings cease and the backache and other reflex symptoms entirely disappear. These are the only classes of cases in which I have advised the use of mammary gland and yet I constantly hear of men using it in cancer, dysmenorrhea of ovarian or tubal origin or due to malpositions of the uterus, and what has astonished me most is its use by some in dysmenorrhea due to stenosis and in cases of amenorrhea.

---

*Read before the New York County Medical Association, May 21, 1900.

The Partoid Gland.—This agent I have used in an entirely different and very much smaller class of cases. It is prepared in the same way, from the sheep, and should be employed in about the same doses as the mammary gland. Its principal action is its power to control ovarian pain and I have employed it with entire satisfaction in these cases of so-called ovarian neuralgia or dysmenorrhea unassociated with extensive pelvic inflammatory disease—cases in which, upon careful bimanual examination, will be found exquisitely tender and usually enlarged prolapsed ovaries with a history of soreness in one or both ovarian regions, often becoming greatly exaggerated a day or two before and during the first day of the period. The history of these symptoms extends over more or less extended periods of time. In these cases I have had astonishing results and have cured in a few weeks patients who have been sufferers for years. The pain disappears in a few days and if treatment is begun two or three weeks before the next period there will be a marked improvement noticed at that time, so that the patient's confidence is won at once and she needs no urging to persist in the treatment. The enlarged tender and prolapsed ovaries soon find their proper position in the pelvis and can be palpated bimanually without pain. When these cases are associated with inflammatory disease of the tubes, such as hydro- or pyo-salpinx with bound-down adherent ovaries, thickened and chronically inflamed tubes I do not think anything is to be gained by temporizing with this treatment. These are operation cases and in my opinion should be operated upon as soon as other well-recognized methods have been tried without avail. I have found that the partoid gland will, even in these cases, have a pronounced and very beneficial influence upon the pain, but it can not, nor can any other agent or method of treatment, overcome the gross structural changes which have taken place and which, in my opinion, call for prompt operation. These are the cases in which I hold that the parotid gland should not be used. The only class in which I have used it with entire success is that of uncomplicated ovaritis, which I have indicated. They are not frequently met with and therefore my experience with the use of parotid gland has not been as large as I should wish. I say these cases are not frequent and the reason I say so is this: I always make it a practice when I am uncertain in regard to the diagnosis to examine my patient under ether before starting the treatment, and I usually find conditions of the nature mentioned above which to my mind call for operation. Uncomplicated cases of ovaritis are quite rare. I would urge therefore that the diagnosis be assured before temporizing in these cases. Only to-day I found by operation an old ruptured extrauterine pregnancy of the left side in a patient to whom I had been giving parotid gland for a few weeks for what I thought was ovaritis. Not getting any result, I insisted on examination under ether and found a mass of circumscribed exudate. Operation revealed the bunched-up skeleton of a two-months fetus protruding from a partially ruptured sac and the remains of the placenta and membranes protruding from another opening in the shape of a grayish macerated round lump the size of a walnut. I would therefore advise that these agents be used only in the classifications which I have indicated, and when there is any doubt about the diagnosis, examination under ether should be insisted on. Finally, I beg to apologize for confining my remarks merely to the clinical side of the subject. I have not had the time or opportunity to take up any experimental work connected with it, but I hope some one else will.

The clinical showing would seem to indicate that experimental work directed along these lines would amply repay any investigator.

THE PROPHYLAXIS AND MANAGEMENT OF INTERSTITIAL NEPHRITIS.*

CHAS. W. PURDY, LL.D., M.D.
CHICAGO.

Strictly speaking, the prophylaxis of interstitial nephritis must include some definite knowledge of the tendencies of the patient to the disease under consideration. This at once opens up a wide field, a large part of which is necessarily speculative or theoretical. Without entering into the speculative field, the pith of this question may be narrowed down for present purposes to the simple interrogatory: Can we predict, with any degree of accuracy, the case or class of cases that, under existing surroundings, will sooner or later develop into or terminate in, interstitial nephritis? If, in our present knowledge, a negative answer to this question is necessary, then the prophylaxis of interstitial nephritis necessarily becomes a myth, for, strictly interpreted, the term has only to do with prevention, and prevention is clearly impossible where we have no definite knowledge of the approach or tendency to disease. If, on the other hand, we are able to classify certain sets of cases that are prolific of interstitial nephritis as their terminal history, then we shall be able not only to render a positive and confirmatory answer to our interrogatory, but also to point out a prophylaxis for the disease.

---

*Read before the Chicago Society of Internal Medicine, June 28, 1900.

In order to compass any tabulation of cases, as above suggested, we must first understand something of the principles of the cause or causes that bring about the disease in question. Now, all our pathologic knowledge of interstitial nephritis, our clinical observation, and the life histories of these cases, tend to the conclusion that the disease is led up to through an overwrought function of the kidneys. Of several hundred recorded cases of purely acquired interstitial nephritis, in my possession, the dominant features of the vast majority of the cases are comprised in the following historical triplet: heavy appetites, sedentary lives, and excessive use of proteid foods. It requires no great amount of reasoning to comprehend the law of nature, that an organ having subjected to it three or four times more work than it was designed to perform, must, if such conditions continue, inevitably become crippled in its functional power comparatively early in the natural span of life; and, moreover, the overwork continuing, the organ, indeed, must break down much within the usual compass of that span.

With regard to the kidneys, it has been determined that their chief function in the organism consists in elimination of nitrogenous waste; indeed, only a minimal portion of such waste ordinarily escapes through other channels—chiefly the lungs. In adult life a healthy man under physical exertion utilizes but about five ounces of proteid food per day. and the kidneys are designed to dispose of the waste of this ratio and remain healthy, other circumstances being equal. It is pertinent here to inquire: What happens to the kidneys of a man who habitually consumes from a pound to a pound and a half of animal food daily? The answer is simple enough, as the sequence of the histories of cases will show, viz., the excessive functional activity of the kidneys results in a chronic hyperemia, the consequent migration of the circulatory corpuscles; and from these, the organization and proliferation of new connective-tissue cells, in the intertubular spaces; as a necessary consequence of these changes, ultimate hardening and contraction of the organs follow—in short, interstitial nephritis.

There are doubtless other causes of this disease, for many conditions of the organism may throw into the circulation more or less foreign matter which the kidneys must remove, and in such cases, the tendency is the same, because the proximate results are the same, viz., overburdened function. But the dominant factor in the causation of acquired interstitial nephritis, for the most part, hinges upon two great central facts, viz., overingestion and overelimination of nitrogen; and these furnish the key and the most important principle to a true prophylaxis of the disease. In many diseases, if we remove the cause, the disease itself will subside; this is not altogether so when interstitial nephritis is once established, because the changes in the organs are of such a nature that they are as permanent as the changes wrought by gout in the joints. On the other hand, however, the removal of the cause in cases of acquired interstitial nephritis, notably in the early stages, often results in bringing the progress of the disease to a permanent standstill, which is well-nigh equivalent to cure.

From the above considerations, it seems clear that in all cases in which we have reason to fear the establishment of interstitial nephritis, the limitation of proteid foods should constitute our first and most essential principle in the establishment of prophylaxis. Reduce the proteid supply by limiting the allowance of animal foods to about four ounces per diem. In other words, butchers' meat should be limited strictly to one meal a day—dinner—and the quantity should not exceed a quarter of a pound. The leguminous vegetables, such as beans, peas, lentils, etc., should, for the most part, be avoided. In case the subject is stout, weighing over 175 pounds, some curtailment of carbohydrates should be suggested, such as the avoidance of oatmeal and the cereals in general, but permitting bread and potatoes. Observation has convinced me that in all cases sugar should be but sparingly permitted. The appetite should be restrained within normal limits. It is safe to say the average individual in robust health, with access to a bountiful table, habitually eats about 40 per cent. more than he uses. It has been found useful to direct such subjects to rise from the table feeling that they could eat more. The subjects of interstitial nephritis have almost invariably been heavy eaters; indeed, we have already called attention to the fact that this is one of the leading causes of the disease. This matter, therefore, should not be overlooked, as it often is, for it is as essential to limit the quantity as it is the quality of food in such subjects.

The next step in prophylaxis is to enforce some systematic daily exercise, in order that the proper ratio of waste products of the economy may be oxidized, thereby entailing the least strain upon the eliminative functions. In some cases an active muscular life is led, and in these this suggestion will be unnecessary. Too often, however, we have to deal with people of middle life, who have been sedentary all their lives. It is in this class of cases that the greatest possible discretion and judgment should be exercised in prescribing active exercise. Indeed, the sudden transformation from sedentary to very active habits in people of middle and advancing life is not without its attendant dangers — dangers which, it seems to me, are either overlooked or not generally understood, judging from the number of aged cyclists one has been wont to see about the streets the last few years. To me such pictures seem as grotesque and out of place as the imaginary one of a company of centenarians in a college campus playing football. In the class of cases under consideration I have always found it more satisfactory, first to adjust the intake to the natural habits of the individual, and, recognizing the difficulties of developing muscles after middle life, to begin with passive exercise and massage until some tone is acquired by the muscles; then walking, horseback riding and golf may be prescribed, with beneficial results.

A somewhat wide experience in cases of interstitial nephritis has conclusively shown me that it is a disease stamped in the strongest manner by heredity. If a series of careful [illegible]gations [illegible]ituted u[illegible] point, it will a[illegible]ar h[illegible] runs in certain families. Family history, therefore, furnishes us a clue to a large proportion of the cases suitable for prophylactic measures against the disease, and wise are both the subject and the physician who avail themselves of the warning afforded by the family history.

The second part of our subject, the management of interstitial nephritis when once established, comprises a field so wide, both in scope and detail, that only a few suggestions are possible in the present discussion. In the early stages the prophylactic measures already detailed are appropriate, only they should be somewhat more rigid. The proteids should be further reduced, say, to two or three ounces per diem; not much will be gained by further reduction. Some prefer to curtail the use of butchers' meat, and permit one meal daily of the lighter proteids, as poultry, fish, sweetbreads, frogs, etc.; milk with some seems to be the sheet-anchor, so far as diet is concerned. I must confess that personally I have never been friendly to milk cures in this disease. In my experience a milk diet disagrees sooner or later with four-fifths of people who try it. The large proportion of sugar contained therein—about an ounce to each pint—deranges the liver, and, moreover, constipation is a common result, thus seriously deranging both digestion and assimilation. At best, milk is but a starvation diet for an adult individual, and certainly it was never designed to nourish people beyond middle age. If a starvation diet must be employed—and at least a reducing diet is often advantageous in these cases—it is easy to supply one from other sources that will offer the patient greater variety and be more acceptable to the digestive organs than milk. For these reasons I rarely employ a milk diet in these cases. It has already been pointed out that the subjects of this disease, for the most part, are notoriously heavy eaters, and in most cases the amplitude of their bodies attests to their industry at the table. It seems impossible to quell or even modify the generous appetites of these people, and, therefore, the more politic and successful method of protecting them against the consequent evils is to order such foods as are bulky or filling but leave little nitrogenous waste. These are numerous, palatable, and, for the most part, easy of access and withal economical. They embrace nearly the whole range of green vegetables, tart fruits, cereals, etc., to which may ordinarily be added fish. The man of ungovernable appetite may be ordered much fat with his food; fat more quickly satisfies the appetite than any other article and it contains only about 2 per cent. of nitrogen.

In advanced interstitial nephritis the chief concern of the experienced physician will be the condition of the heart. Some years since I made a careful study of those conditions of the kidney which have been grouped together under the term of Bright's disease, until I flattered myself I was fairly well informed upon the subject; I soon found, however, in practical experience, that the majority of my cases of so-called Bright's disease died directly from heart disease. Since then, whatever measure of success I have had in the management of interstitial nephritis when once under way I attribute largely to my management of the associated cardiac disease. As is well known, at least 75 per cent. of the cases of interstitial nephritis are accompanied by a progressive enlargement of the left cardiac ventricle, and I have no hesitation in stating that in the large majority this heart lesion will vastly outrun the renal disease, and destroy the patient's life long before he would succumb to the renal lesion, unless special means be taken to prevent it, and for the following reasons: In the first place the kidneys are double organs, either of which, upon appropriate diet, will permit the extension of life indefinitely; in other words, the functional power of either kidney is sufficient to maintain life indefinitely under ordinary pressure. The anatomical changes in interstitial nephritis, as a rule, are very tardy in progress, and of such a nature as not to materially interfere with the function of unaffected areas of the organ. Consequently, the disease may, and often does, progress twenty or thirty years, until, indeed, the kidneys are markedly contracted, yet a fair degree of functional capacity remains—sufficient to permit life to continue indefinitely and in comparative comfort.

If, on the other hand, we watch the cardiac changes, when marked, we shall note an altogether more rapid and serious set of phenomena to which *per se* the patient must succumb. In consequence of increased friction in the circulation, the left cardiac ventricular wall enlarges to meet the extra demand upon its muscular power; the ventricular wall gradually becomes thickened, increasing the left cardiac area in the chest to 12, 14 or even 16 cm. from the midsternal line. Now, mere hypertrophy of the left cardiac ventricle, at first sight, would not seem so serious a matter, but wait and observe. Every case of cardiac hypertrophy, if its causes continue, sooner or later passes into degeneration of the cardiac muscle, after which the changes are rapid, widespread and lethal in tendency. Cardiac dilatation, with consequent valvular leakages, regurgitation into the lungs entailing *edema pulmonum* or pneumonia, and engorgement and enlargement of the liver, and dropsy are a few of the consequences likely to succeed the above phenomena without delay. I am well acquainted with these morbid phenomena, because it is at this stage of the disease that the specialist is often ushered in at the front door—all hope having shortly before been ushered out by the side door. If we wait until this stage of interstitial nephritis is developed, one management is practically as good as another. It therefore becomes pertinent to inquire what can be done to prevent advanced cardiac complications in interstitial nephritis? I answer: Much, very much, can be done.

There is no class of diseases familiar to the profession in which more can be done to relieve and prolong life than in cardiac diseases, thanks to very recent advances in our knowledge upon this subject. Cardiac complications of interstitial nephritis form no exception to this statement, provided treatment is begun sufficiently early. The first principle in the management of the cardiac complications of interstitial nephritis should consist in modifying the abnormal friction in the circulation. If this is done the cardiac hypertrophy will subside, provided that it has not gone too far and that the arteries have not become extensively atheromatous. The area of cardiac dulness must first be mapped out in all cases of interstitial nephritis; if the left area does not exceed 12 or 13 cm., as measured from the midsternal line, the rule obtains quite constantly that upon a non-nitrogenous diet, as rigid as we can draw it, coupled with saline laxatives, the hypertrophy will subside rapidly, thus avoiding the more advanced and more threatening cardiac danger. Over and over again, I have succeeded by strict measures in reducing the area of the left ventricle by at least 3 cm. in six months' course of treatment. A left ventricle, however, once decidedly hypertrophied in interstitial nephritis, so that the left area measures 14 cm., strictly speaking, probably never quite returns to its original or normal measurement of 9 cm., but usually remains at about 10 cm., at least such is my experience, nor have I usually found this slight remaining thickening any special bar to a subsequent long and efficient cardiac life. Some tension in the circulation remains, it is true, probably due to changes in the arterial walls, but moderate tension only tends to restore the waning balance of renal excretion.

Let us suppose, however, that the cardiac complication has reached a more extreme degree before the case has come under observation, and that the left cardiac area measures 15 or 16 cm. from the midline. We are now face to face with altogether different conditions, in most cases including more or less dilatation of the left ventricle, perhaps with some leakage of the mitrals; in short, degenerative changes have begun in the cardiac muscle. The physical forces of the heart have now become reduced below par, and we no longer find evidences of exalted circulatory power. The urine falls off in volume, the patient no longer rises at night to urinate, the pulse grows weaker, though the arteries be hard.

The indications now are clear to improve the tone and nutrition of the heart, to relieve it of as much of its labor as possible. With the view of relieving the strain upon the cardiac muscle, in addition to rigid dietary measures, the small vessels should be dilated by means of the iodids and nitrites. A moderate dose of digitalis, say ten drops of the tincture, morning and evening, tends to improve cardiac nutrition and tone, the latter being much assisted by the use of strychnin. Absolute quietude should be enjoined for from four to six weeks, until the heart has regained its tone, or at least is in a measure equal to its work, after which quiescence is likely to be rather harmful than otherwise. However, before permitting the patient to get about again unrestrained, a course of cardiac gymnastics, after the method of Schott, coupled with, or followed by, the Nauheim baths, is often of the greatest benefit. The extremely hypertrophied hearts, under present consideration, can never be reduced to near normal dimensions, attended, as they usually are, by more or less dilatation, consequent to cardiac degeneration; nevertheless, the degree of cardiac power and tone that can be restored in well-managed cases is often remarkable. Not long since such cases were considered absolutely hopeless, even of temporary improvement. I have succeeded, however, in a fair proportion of such cases, in securing to the patient a few years of comparatively comfortable life.

When once dropsy sets in and becomes established, as a rule, the beginning of the end is reached. Confinement to bed is now imperative, coupled with cardiac tonics and stimulants, such as digitalis, strophanthus, etc., in full doses. There is no hope of re-establishing the renal function unless some power can be restored to the circulatory forces. Too often we are obliged to fall back upon diaphoretics in order to assist the kidneys in elimination, but the fight from this on is always a losing one.

The present discussion does not permit of sufficient time to enter into the many additional measures to be employed in the management of interstitial nephritis; perhaps a future occasion may present itself to consider these. I have purposely directed the present discussion along what may be considered, in part at least, unusual though important lines, viz., the cardiac complications of the disease. In closing, I would state as my strongest convictions, based on careful observation, that, as a general fact, he who most skillfully manages the cardiac complications of interstitial nephritis in all its stages will best succeed in prolonging the lives of his patients.

[For discussion see page 248.]

HOSPITAL AND WARD CLINICAL LABORATORIES.*

C. N. B. CAMAC, M.D.

NEW YORK.

When I was given the opportunity some months ago by the chairman of this Section to present a paper before the Association, I was and am still interested in the subject expressed in the title of this paper—"Hospital and Ward Clinical Laboratories." I hesitated, however, in bringing such a subject before you, as I felt that a report upon work done along medical lines would form a more appropriate paper. I submitted this question of the propriety of the subject to your chairman, and upon receiving his approval and encouragement felt reassured.

I feel, nevertheless, that a subject touching the administration of a hospital, as this does, must be discussed by those who have experience in hospital management. The points, therefore, set forth in this paper represent the immediate needs of the visiting physician and teacher; these points, however, must be placed before those who are competent to speak for the administrative side of the hospital. I trust that I have made it clear at the outset that I am speaking from the standpoint of the clinician.

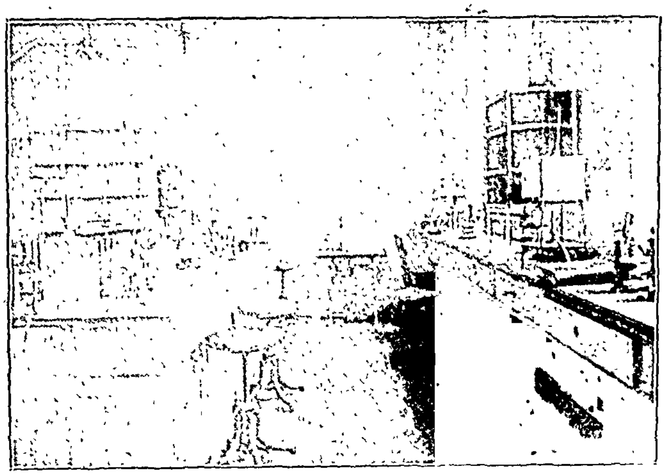
As one reads the reports upon the epoch-making contributions to medical science, one is impressed by the exalted estimation which ushers in many, but not all, of these; then how the voices of critics disparage these estimates, which perhaps may have been the creation of other critics, and then how the contribution settles down into its right place to be a great or a small part of the whole. As each new branch of scientific medicine has come into existence the same enthusiasm has flustered and shouted about its birth, claiming for it all manner of honor and usefulness.

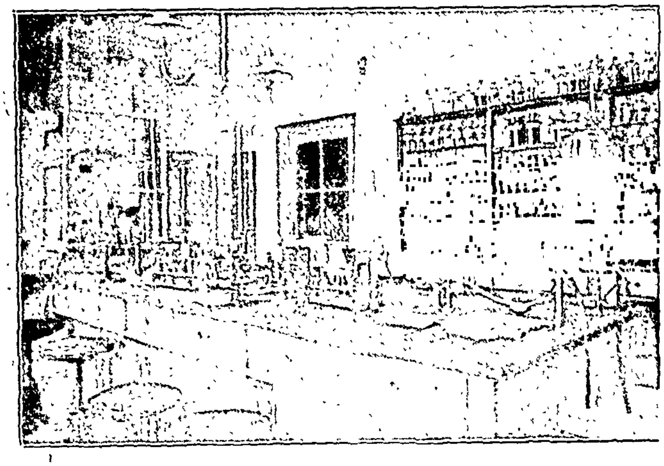
Histology, embryology, bacteriology, the systematic study of pathology, etc.—and the same is true of the subdivisions of these subjects—each in turn at its inception was declared to be the future revolutionizer of medicine. Each has settled into its proper place to be a part of the whole structure, each stone of which depends upon its fellow for support; or to select a simile more familiar to our thinking, it would seem to follow the division of labor or the specializing of functions, each cell, each part, doing its share and yet working in conjunction with every other part. When Laennec, and, later, Louis, introduced the system of physical diagnosis, the most exorbitant claims were made for it. The stethoscope, at first the oracle of all the secrets of the chest, later became the retreat of the bluebottle fly, and then again the recognized instrument, with its limitations, of the clinician. So with the clinical thermometer, the hypodermic needle, the fluoroscope, the radiograph, etc.; so also with the findings of the clinical laboratory.

Rarely in our science is it that any one finding is the open sesame to the secrets of disease. Excepting, perhaps, the finding of the tubercle bacillus, the malarial parasite and a few others, no observation in medicine alone tells the whole story. Because an observation represents but a fraction of the whole truth, many clinicians have been impatient with the methods which enable us to obtain that fraction. Because the methods which enable us to detect an anemia do not also detect the cause of the anemia, the methods are said to [illegible] iy; [illegible] the tubercle bacillus is sometimes not monary tuberculosis exists, the search, some clinicians would say, need only be made if the clinician wishes to leave no stone unturned. Because the serum diagnosis of typhoid fever is not to be detected until the fifth day, and sometimes not till much later, is this fraction of the truth to be discarded? May there not be here some new truth, the full significance of which we have not as yet appreciated? Because, by the aid of a clinical thermometer, a definite ratio between pulse, respiration and temperature can be determined, we do not abandon it when, as in scarlet fever or pneumonia, we find this ratio disturbed; on the contrary, we interpret the finding with new significance as an additional aid to diagnosis. We do not omit auscultation when percussion seems to tell us the whole story. So, though our physical examination may appear to suffice, our microscopic and bacteriological examinations must, too, be taken in conjunction with these findings, a consensus of opinion taken, and our diagnosis made accordingly. Each observation goes to make up the whole—the clinical thermometer, the stethoscope, the blood examination, each employed in turn, no one complete in itself, but the complement of the others. There is, therefore, no claim for the clinical laboratory beyond that it contributes essential facts, which, taken together with other clinical findings, enable the physician and surgeon to arrive at the truth or nearer *the truth*.

---

*Presented to the Section on Pra[illegible] Fifty-first Annual Meeting of the A[illegible] held at Atlantic City, N. J., June 5-8, 1





Prof. V. Jaksch's Clinical Laboratory, Prague.
Microscopical Laboratory.

If one takes a broad view of the development of medical knowledge it will be seen that now is the full time for the birth of this new child of science—the ward clinical laboratory.

HISTORICAL OUTLINE OF LABORATORIES.

The time has passed in which learned men were content with mere logical conclusions, high-sounding names and mysterious pursuits. The alchemist's articles of faith were:

1. There exists a preparation, solid in form and red in color, called the *philosopher's stone*, the *grand elixir—majus magisterium*— the *red tincture*, which, when it is placed in very small doses on melted liquid silver, mercury, lead, or some other common metal, causes a transmutation of the same into gold.

2. The same preparation, used in very small doses as a medicine, cures all diseases, rejuvenates the old and prolongs life—wherefore it is called the *panacea of life*—also because it contains the essence of gold—aurum potabile.

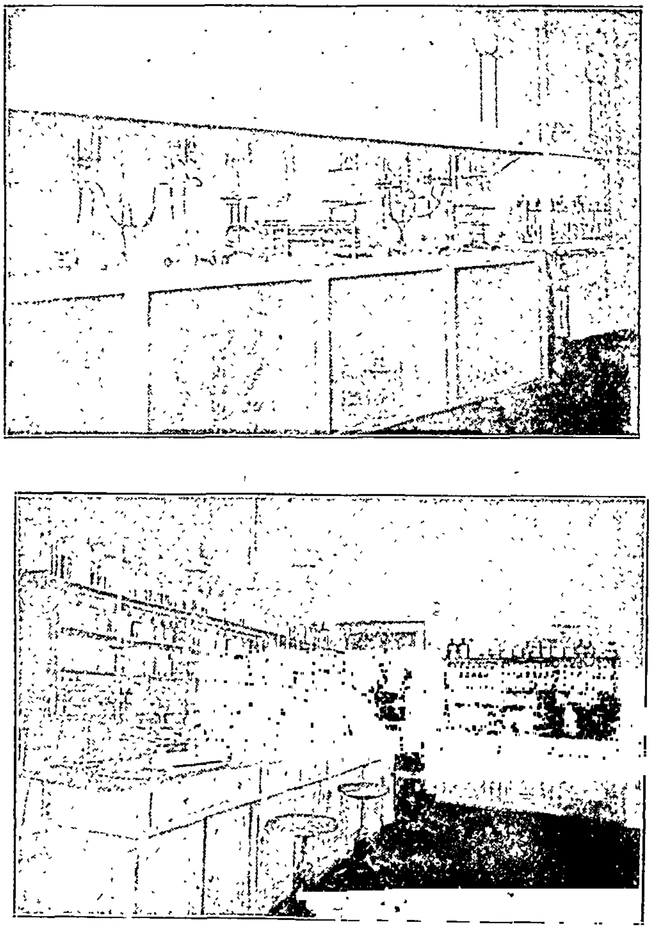
3. There is another preparation, of a white color, called the stone of the second degree, the *little tincture—minus magisterium—the white tincture*, which is equal to the first in half a degree of perfection and changes the common metals to silver.

This creed, the ignis fatuus of the alchemist, leading him blindly through the world of facts, was replaced, alas! by that other, the Philosopher's Stone, the Vital Force, the Pneuma, and finally by the torch of truth, flooding with light the dark places. This torch of truth is the determination of the human mind to see and therefore to know; to see, not through the oft-befogged medium of logic, but through the clear atmosphere of experiment. When the human mind determined this—and it has not been long that it has thus determined so—the real scientist, he who would know the truth, had his birth. Superstition gave place to unrestrained investigation; the magician became the scientist; the alchemist became the chemist. With the *purpose of experimenting* in the human mind the necessity for workshops became evident. From Stahl and Lavoisier, from Steele and Berzelius, from Gay Lussac, giving inspiration, and Liebig, the mind turns to those who worked more in medical lines, to Harvey, Descartes and Haller, who can not be given greater place as founders of the laboratory than the great chemists before mentioned, for with them it was that the spirit of investigation and experiment gave life to the whole movement. Hand in hand with the establishment of chemical laboratories but more encumbered by superstition, came the anatomical theaters; farther along the line of time the clinic, and then in the early part of our present century the physiologic laboratory—the first of which we find at Breslau in 1825 (Purkinje), Vierordt, Tübingen, 1864-5—which, as Dr. Welch says, and which might well be said of all laboratories, is productive of a knowledge, "the best corrective of pseudo-scientific, irrational theories and practice, in medicine." Then followed the development of the first pathologic laboratory in Berlin, by Virchow, in 1856.

In the opening of the William Pepper clinical laboratory at Philadelphia, 1896, Dr. Welch quotes Virchow as having said: "In the seventeenth century, anatomical theaters; in the eighteenth, clinics; in the first half of the nineteenth century, physiological institutes; so now the time has come to call into existence pathological institutes and to make them as accessible as possible to all." Since then has not the clinical laboratory reached its limit of usefulness, and now, is not this the time when all this vast amount of work, clinical, anatomic, physiologic and pathologic, shall be applied to the bedside? Is not this the time for the practical application of all these researches?

I am quite aware that the idea of practical is as distasteful to a certain class of scientists as is the word "wine" to the temperance lecturer—alcohol may be rubbed in from without, must not be taken internally; such scientists remind one of Carlyle's description, in his "French Revolution," of Madame Momoro, whom the French convention of 1793 enthroned at Notre Dame as the Goddess of Reason. Carlyle says of her, she made one of the best goddesses, but her teeth were defective. This kind of science is a beautiful thing, but it lacks the practical bent, it lacks teeth, without which it can not feed upon that which gives force to the whole.

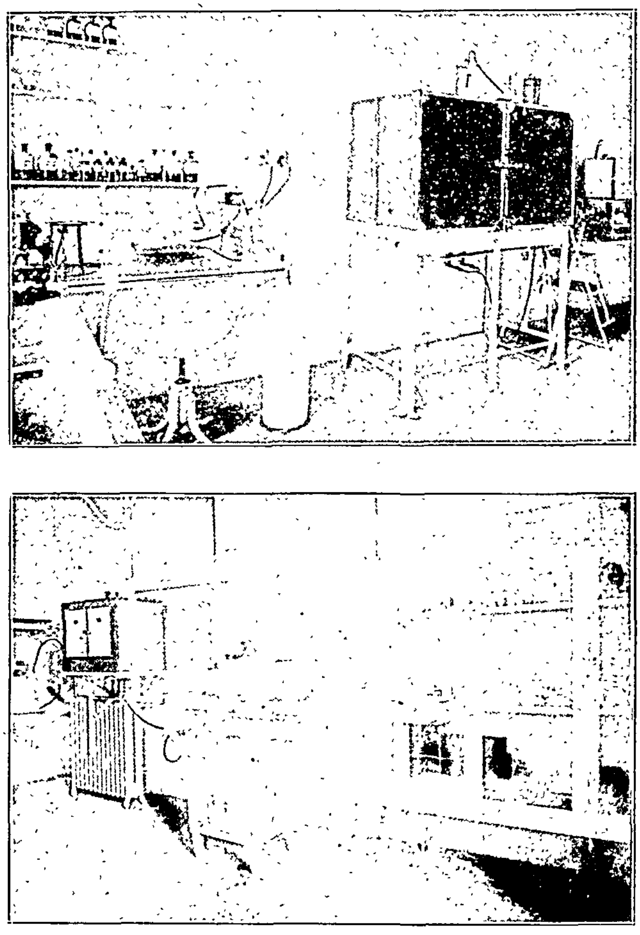
Shall we go back to those dark days, when it was merely a quest for the solution of a mystery, the finding of the majus magisterium, or have we the larger purpose of applying this solution, of interpreting this discovery? Shall our knowledge be an ornament or an instrument? If the spirit of quest for truth quickened the work of Bernard and his confrères, Gréhaut, Du Montpallier, Malassez and d'Arsonval, in their ill-equipped shops, the application of these truths should quicken our work to-day.



Prof. V. Jaksch's Clinical Laboratory, Prague. Chemical Laboratory.

The subject, therefore, of our investigation as clinicians is not disease in the abstract, but the sick man and woman and the sick child. It is not the study of the principle underlying the staining peculiarities of the tubercle bacillus, but the availability of this method in the detection of tuberculosis in this and that form of the disease. It is not, therefore, the sputum, for example, alone that we examine; it is this in conjunction with the physical finding, the temperature chart, the degree of emaciation, etc., to be made only in the sick-room by the patient's side. Our workshop is therefore the sick-room, the hospital ward, the dispensary.

DIFFERENCE BETWEEN PATHOLOGIC, CLINICAL AND HOSPITAL WARD LABORATORIES.

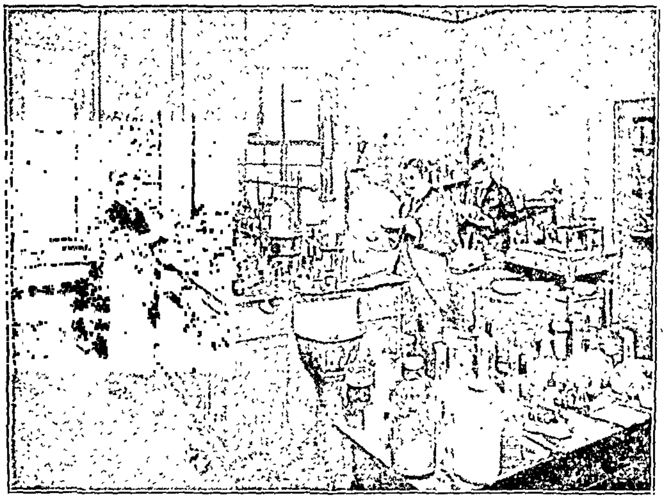


Prof. V. Jaksch's Clinical Laboratory, Prague. Bacteriological Laboratory.

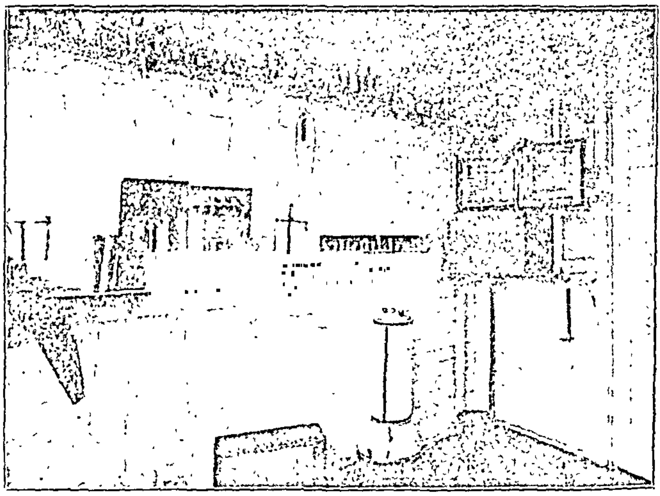
By thus recording conditions in detail, information upon disease as a whole may be obtained by bringing together these records. The subject of this paper, it will therefore be observed, is not the clinical laboratory, but the hospital and ward clinical laboratory. The former is a recognized factor in medicine to-day. In Berlin, Prague, Vienna, Munich, Leipsic, Paris, London, Philadelphia, Boston, Baltimore, New York and in many other cities are to be found well-equipped clinical laboratories, all having sprung into life in the short space of about 20 years. Among the first of these was that of Von Ziemssen, in Munich (1895), and that of Curchman, in Leipsic (1892). Not so numerous are the hospital clinical laboratories. There would at first sight seem to be a difference without a distinction between these terms. There is, however, this clear distinction: the clinical laboratory, now of some years' standing, is the offspring of the anatomic, chemical, pathologic and physiologic laboratory, and the hospital clinical laboratory is the child of the clinical laboratory—each separate from the other, yet dependent on, and a direct outcome from, the other. It may be looked on as a process of simplification. Large problems worked out in the chemical, anatomic, physiologic and pathologic laboratories have been reduced to simple methods, applicable to the detection of disease *per vitam*. The clinical laboratory has taken up these and still further simplified the methods until the hospital or ward clinical laboratory may apply th[illegible] the bed. The pital clinical laboratory is the workshop where the methods planned and perfected in the other laboratories are applied and given a practical test. To make this difference more clear, I show photographs of the elaborately equipped clinical laboratories of Profs. Von Jaksch, Ewald and Leyden, so as to compare them with the simple ward laboratories.

OBJECTIONS TO LABORATORIES.

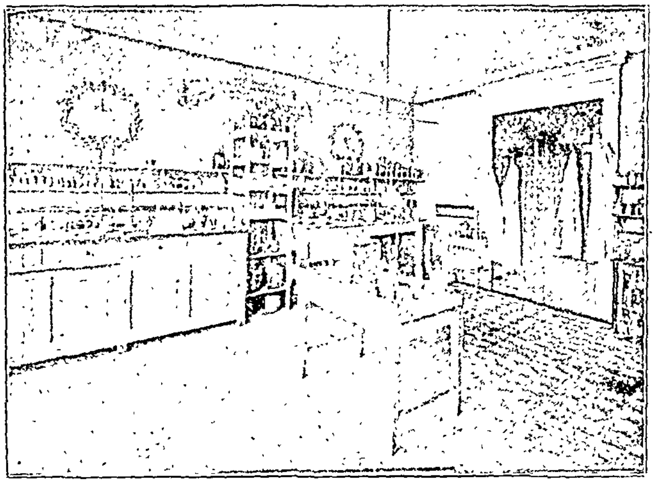
But, it will be urged, do we need hospital or ward clinical laboratories? Are they not the adjuncts of wealthy medical schools and hospitals only? Are they not a scientific luxury? Can it be said that the facilities afforded by such laboratories are luxuries? If the patient who escapes operation for supposed appendicitis because a moment before the operation the blood was found to contain malarial parasites; if the patient lying in supposed typhoid has a needle inserted into the liver, where an amebic abscess is found; if these patients do not benefit by such laboratories, they may be termed luxuries. They are essential, however, if *only* to spare the typhoid ulcer the unlimited diet of quinin. I select these cases from those actually occurring in hospitals where facilities for clinical microscopic examination were not supplied and where such procedure is not considered a refinement.



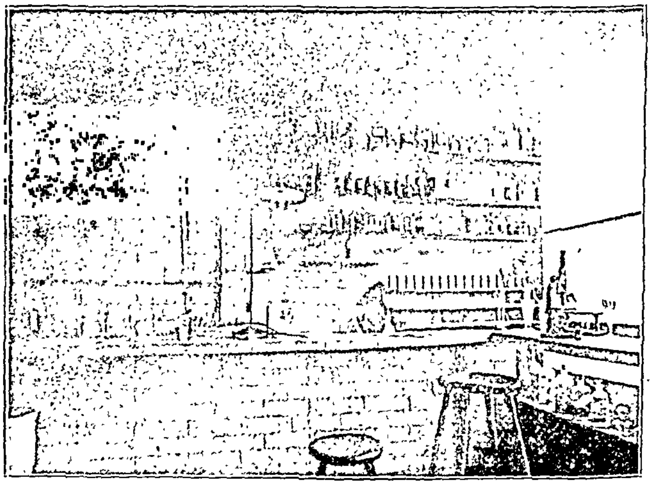
Professor Leyden's Clinical Laboratory, Charité, Berlin.



Toronto General Hospital, Clinical Laboratory—east side.



Professor Ewald's Clinical Laboratory. Augusta Spital, Berlin.



Toronto General Hospital, Clinical Laboratory—west side.

There are, however, those who will still object, and from information obtained in conversation and otherwise, the objections would seem to fall under the following four heads: 1. They are not necessary because diagnosis can be made quite as satisfactorily without these tests. "Scientific luxuries" would, I think, express the opinion of those who raise this objection. 2. They require space. 3. They are expensive. 4. The hospital interne is busy enough without putting this extra work upon him.

The first of these objections, that they are "scientific luxuries," has been already dealt with. It is well, however, to repeat that these methods are taken in connection with all the bedside methods known to clinicians, and no claim of an "all-sufficient" is made for them. The physical examination of the chest is not to be abandoned because the tubercle bacilli are found in the sputum. It is important to impress this, for visiting physicians have complained, and not without ground, that the internes consider these laboratory examinations all-sufficient, and grow lax in making their physical examination, and less acute in their observations. This is a misuse and abuse which does not in any way diminish the value of each observation. Let it be clearly understood that there is no claim of all-sufficient in this work. The very spirit of the movement in favor of ward laboratories is that the microscopic work should be brought in greater proximity to the patient, and the finding be thus taken in connection with and considered a part of other clinical findings.

The second objection is that they require space. The clinical laboratory, with its complicated chemical apparatus, spectroscope and polariscope, nitrogen-estimating apparatus, etc., does require space. But the distinction between the clinical laboratory and the hospital and ward clinical laboratory already pointed out, must be borne in mind. Only the perfected and simplified methods and apparatus have place in the hospital and ward clinical laboratory. This apparatus and these methods are of such simple nature that they can be transported to the bedside. It does not, therefore, require much space to accommodate them. With the hearty co-operation of the authorities, the writer established such ward laboratories at Johns Hopkins Hospital in 1896. and at Bellevue Hosptal in 1899. The area required for this ward laboratory is about 6x6 to 10x10 feet, a window being the only essential. Indeed, a window and table are the only essentials in the matter of space. While running water and gas are helpful adjuncts, the ordinary water-bottle and spirit-lamp are all that is necessary. Probably no part of a hospital is more modest in its demands that the ward laboratory.

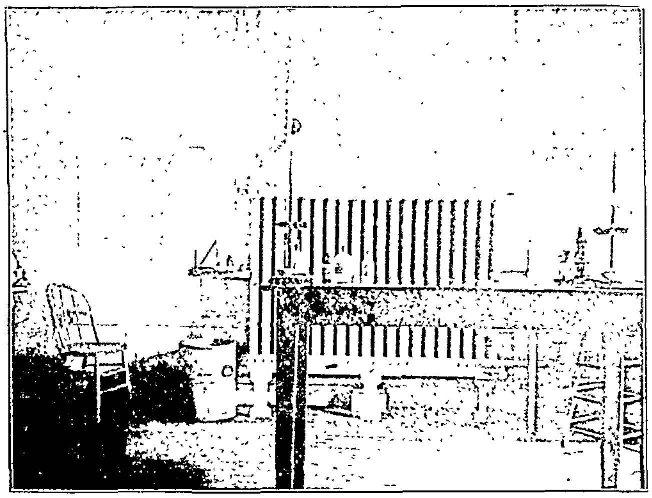
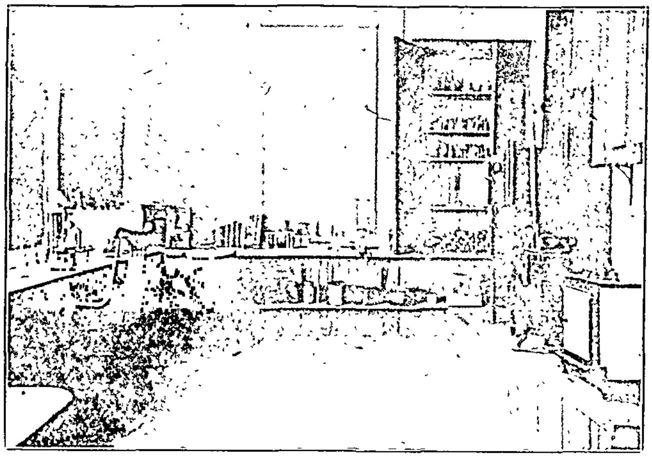
Room, 12x12 ft. (about.)



Johns Hopkins Hospital, Baltimore.
Special Research Room.

I should like to take this occasion to express my appreciation of the encouragement given in the establishment of such ward laboratories by Drs. Osler and Hurd, at the Johns Hopkins Hospital, and by Drs. W. G. Thompson and C. L. Dana at Bellevue Hospital. I have just learned from Dr. Beverly Robinson that such ward laboratories are shortly to be established at St. Luke's Hospital, New York City. I also learn that the Royal Infirmary at Edinburgh, and St. George's Hospital, London, have similar ward laboratories. In the clinics of Profs. Leyden, Senator, Naunyn and Gerhardt, in Europe, these ward laboratories are in use for the minor examinations.

We may, therefore, eliminate the objection of "too much space required." It is understood that there are in addition to these the largely equipped laboratories for more extensive work, but these latter are part of the teaching institutions connected with the hospital. The small laboratory just described is a distinct feature of the ward and its administration.



Victoria Hospital for Sick Children, Toronto, Canada. Clinical Laboratory—South End.

Ward Laboratory. Bed on left. Cabinet for Reagents and Apparatus on right.

That such laboratories are expensive, constitutes the third objection. I have carefully gone over the bills connected with the establishment of the laboratories above mentioned, and find that $300 will fully equip such a laboratory. Included in this are two large items —a microscope with an oil-immersion lens and a cabinet in which apparatus is to be kept. These two together would come to $125 or $150 [illegible] hile c[illegible]rable modification can be made in [illegible] microsc[illegible] is a necessary expense, [illegible] but l[illegible]tle. Most hospitals, [illegible] as microscope, at least, so that we will find that already provided. Glass-top tables, with green felting beneath, have proved most satisfactory in both Johns Hopkins and Bellevue. This is not very expensive—$9 to $10 for a table 5x3 feet. This allows of the table being washed off freely, keeping the appearance of the laboratory clean. It is surprising what an influence this simple provision has on those working in the laboratory to keep it clean. Such is the effect of this that it has done away with what was a very serious objection, namely, the presence of a dirty laboratory directly in the ward. The same cleanliness observed in the operating-room and ward must be observed in the ward laboratory. A rather feeble, but in appearance forcible, objection has been raised by some authorities that patients may drink some of the poisonous reagents. This is overcome by having these reagents locked away in the case, as are the drugs.

A wretched difficulty, which one is almost ashamed to mention, but which nevertheless exists, is the appropriation of apparatus by members of the interne staff. This matter scarcely comes within the province of this paper beyond mentioning it and calling attention to the proper authorities for its correction, namely, the examining board, in ascertaining more correctly the character of applicants for the position of interneship.

The maintenance of the laboratory can well be accomplished on $50 a year. Dr. Fritcher informs me that at Johns Hopkins Hospital the cost of maintenance is $75 a year. Dr. Cabot kindly informs me that $30 is all that is required for the maintenance of his laboratory at the Massachusetts General Hospital, Boston. It has, I hope, been satisfactorily shown that the laboratory is a necessity; that it requires little space, and that it is moderate in expense both to establish and maintain.

The fourth objection, that the clinical tests occupy too much time, is a serious one, and requires much more discussion than can be given here. The hospital interne to-day is much in the same position as the medical student of a few years back, who was allowed to graduate in three years. New subjects, histology, bacteriology, pathologic histology, hygiene, experimental physiology, etc., were added to his requirements, but the length of the curriculum was not increased commensurately with this increase; consequently his medical course was a feast of reason, a large proportion of which he was gulping down and never digesting. The uncomplaining, enthusiastic, conscientious interne does not realize until nearly the end of his interneship that a large part of his time has been spent in history taking. Blood work takes time, and if attempted it is slurred. This is because the work of to-day in hospitals is far greater than that of ten years ago, but the interne staff has not been increased commensurately with the increase of work. The remedy for this is that there should be in large hospitals a bacteriologist interne, and a clinical microscopist and a chemical interne. This position in small hospitals could be combined in one interne. But it is a fact beyond dispute that the senior and junior internes, and the interne in charge of a ward, can not possibly be responsible for the bacteriologic and microclinical work and keep their records up at the same time. The hospital interne is a very responsible officer, not only from a humane point of view, but from a scientific viewpoint as well. He is the observer constantly on hand; from his observations, carefully noted, we should be able to read the story of the disease. Unless his work be so ordered that the visiting physician can insist upon

such records; his notes are nothing more than fiction. The observations and records should be in the hands of the senior, junior and ward internes, the bacteriologic and microclinical work being done and recorded with equal care by one or two internes, whose sole duty is this work.

ADVANTAGES OF SUCH LABORATORIES AND WORK.

It has often been contended that good work will be done in spite of poor surroundings. This must be admitted even in those branches of human pursuit depending most on inspiration. The master mind makes its own way. Handel and Beethoven on the expressionless spinnet composed music which the improved instruments of to-day show must have existed in the minds only of these great musicians; while the commonplace mind of Nero must needs have Rome aflame for inspiration which failed to appear in even so terrible a spectacle. This is indeed true, but where there is one Harvey and one Bernard there are a hundred commonplace minds which, if given some encouragement, will develop into valuable observers. The laboratory, then, increases our army of workers one hundred fold. Need we look further for an explanation for the vast strides made since laboratories have become recognized parts of medical schools. Another advantage of such laboratories is the accuracy of diagnosis and the directness of treatment. This is beyond dispute and may be dismissed with the mere mention. The only opposition, however, to this statement is that negative results so often accompany the microscopic examination. While this is true, yet when the negative finding is not in itself an aid as excluding some suspected condition, the constant observation leads not infrequently to the finding of objects not at first discerned, and which in themselves constitute diagnostic aids. The development of the eye is yet in its infancy when its field of vision is that seen through the microscope—when through generations the eye has become accustomed to observe this new world, may not new objects become discernible? Should not, therefore, the spirit of constant observation be inculcated and every object of well-known significance be noted? This brings us to the third advantage of such laboratory work—accurate taking of records. "A book," says an editorial in the *Journal of Science*, "at best is but a useful adjunct in science." It is, however, the heritage of one generation to another, and it is the starting-point for the next observer. The German mind, content to concentrate itself upon one small but essential part of the structure of science, until it be well formed and set in place, is a greater contributor to the edifice than he who throws ever so strong a light upon that portion already built. The well-taken record is the material from which the stones for further construction must be selected. What better place than the bedside laboratory for obtaining the material for such construction? Knowledge is not acquired, as Ambrose Paré says, "by sitting in a chair and thinking, but by years of hard, practical labor." And we may add, as he indeed added, by making careful records. A few practical clinical books have been placed in the ward clinical laboratory, and we have prepared record sheets containing a complete list of all objects to be seen in the various subjects of clinical, microscopic, bacteriologic and chemical observation, whether they have a known significance or not. The object of such records is that we may later draw conclusions coupling these observations with the other bedside findings.

Is such record-taking confined to the bedside—to the ward—may it not with advantage be extended to the dispensaries? Dr. Cabot, in the Massachusetts General

Hospital, has already done this, and his photographs, which he has kindly sent me, show such a workshop in the outpatient department during the busy hours of the dispensary. While the writer was in charge of the heart and lung clinic of Bellevue Hospital, no case of suspected pulmonary tuberculosis or malaria had a diagnosis made until the sputum in the one case, and the blood in the other, were examined. As no facilities for microscopic work were obtainable in the dispensary, it was necessary to take the patient for this purpose across the street to the Loomis Laboratory, and in eight months, with one assistant, 129 cases were so examined.

System of Records to be Employed in Bellevue Hospital, New York City. (Cornell Division.)

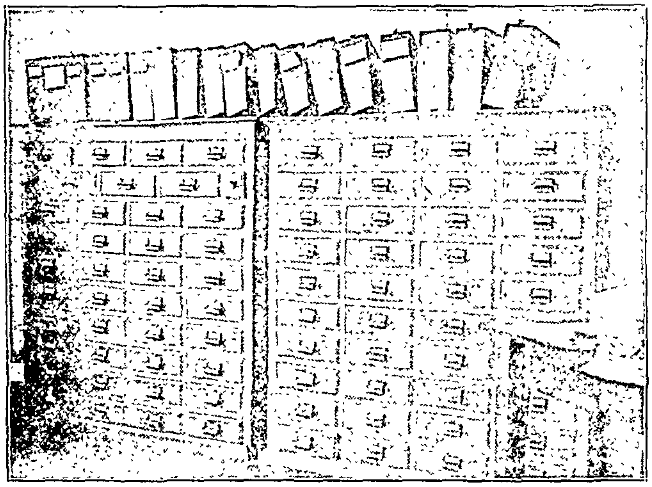
Among the cases thus examined were estivo-autumnal malaria, having its origin in New York City; Hodgkins' disease, which was subsequently followed to autopsy; lymphatic leukemia, splenomedullary leukemia, Addison's disease, also followed to autopsy; empyema, abscess of the lungs, pneumoconiosis, in which steel filings formed the dust element and gave rise to a fibroid phthisis; tubercular leprosy in a youth 16 years old, from whom the lepra bacillus was readily obtained; these, besides many cases of malaria of the ordinary type, and anemias formed the interesting findings. May we not from such records detect the beginning of disease, while yet not sufficiently advanced to incapacitate the patient? May not diseases called rare, because seldom under systematic observation, be thus found frequently enough? Have we not examples of this in the leukemias, malaria, Addison's disease and others? Is it unreasonable to conclude that, with facilities for such work and adequate assistance, valuable records could be obtained from the outpatient department? The last advantage which is to be noted in these laboratories is, perhaps, when combined with that of the records, of vast importance. I refer to the following of cases to autopsy. The pathologist is independent of the clinician, but the clinician reads the answer to all his questions in his observations and notes at the autopsy table only. The break in the chain between the clinician and the pathologist has existed only since the pathologist became a specialist. The busy practicing physician who is a hospital visitant has not the time to follow to autopsy his cases. He should, have the benefit of well-taken records and the diseased viscera should be preserved and shown to him. The link connecting these important departments, clinical and pathological, seems to be the department of clinical pathology. The officer in charge of this work should have access to the wards and the autopsy room. He and his assistants should watch the cases throughout, interpreting the findings at the bedside, by those in the autopsy room. As one attempts to estimate the value of such a system, well carried out, can doubt arise that the time is ripe for a ward clinical laboratory? Is not the clinician falling behind the pathologist in this matter of laboratories? Is he not depending too much upon the report of the pathologist, examining at a distance an isolated bit of tissue? Does the geologist, content with the small bit of stone, chipped from the rock, separate himself from exposed strata? Are the flora and fauna to be studied in artificial surroundings only? Are not the ward and the sick-room the laboratory of the clinical pathologist?



Johns Hopkins Hospital, Baltimore.
Record Room.

The purpose of this paper, however, will have been lost if the impression is given that here is a new specialty. On the contrary, this is an essential part of the clinician's work, and the purpose is to bring to the bedside the laboratory, which has threatened to become, like the pathologic laboratory, separated from the bedside. It was the undisputed right of the pathologist to shut himself away in his laboratory, but it is equally the undisputed obligation of the clinician to carry on his work at the bedside. The points, therefore, which, may I hope, have been brought forward in this paper, are: 1. That *the time has come for a ward clinical laboratory;* that such should be established and maintained; that the requirements in space and expense of establishment and maintenance are of such modest proportions as to be within the reach of the smallest hospital. 2. That these workshops, being in the neighborhood of the patients, must be kept scrupulously clean. 3. That two internes, a bacteriologist and a microscopist who is also a chemist, should, upon proper examination, be appointed in larger hospitals to have charge of these laboratories. The duty of these internes should be to make examinations pertaining to the work for which they are trained; to keep careful records of these findings during the stay of the patient in the ward, and if the patient come to autopsy to take brief records of the findings. 4. That the obtaining of the autopsy and the bringing of the history of the case to the autopsy be a part of the duty of these internes. 5. That a similar laboratory, with a specially appointed physician, be established in the outpatient department.

I wish to repeat that all these suggestions are from the standpoint of the clinician and teacher, and the discussion by and the approval of those versed in hospital management is necessary.

BLOOD EXAMINATION.

ITS VALUE TO THE GENERAL PRACTITIONER.*

M. H. FUSSELL, M.D.
PHILADELPHIA.

I believe that the vast majority of the practitioners of medicine never make an examination of the blood of their patients unless such an examination is suggested and carried out by a consultant. The reasons for this may be many, but the following I believe to be the most important: 1. Blood examinations as practical diagnostic measures are of comparatively recent origin; consequently, men who graduated fifteen or more years ago were not taught the value of such examinations, or how to make them. Unless such members of our profession have had the subject forced upon them by teaching, or by continued intercourse with men trained in such work, they are quite unlikely to take it upon themselves. 2. Blood examinations, like all other valuable diagnostic measures, take time. The general practitioner is hurried; in the town competition is great; and those who depend upon the practice of medicine for a livelihood are apt to become careless about the use of these finer diagnostic measures, and depend upon less certain means of diagnosis. To once slur these valuable agents is to learn to gradually discard them, to the great detriment of ourselves and our patients. It is certain that in many cases examination of the blood is quite as important as, indeed more important than, examination of the urine. It is now an accepted fact that no case is thoroughly studied without a urine examination. I believe it will soon be accepted by the general practitioner—as it is now recognized by the specialist—that a blood examination is equally as important for a thorough study of our cases.

That such examinations are possible and practical for one who practices medicine for a livelihood and not as a pastime, I am personally certain, for I am a practitioner and by no means a hematologist; I have been slow in learning, but now make almost daily use of this most valuable help. Without the aid of an assistant, I have made examinations of blood in a practical way just as I have the urine, and I feel that it *helps me as much* in my daily work. I have as yet been unable to examine the blood of every patient, but I trust that the time is not far off when I can do that in my work. I do, however, use blood examinations in every obscure case, with the greatest possible benefit. I was led to the general use of examination of the blood by the recognition of my own mistakes and by the mistakes of others where no such examinations were made.

One of the most common errors is that of considering all pale individuals as anemic. Many mill-workers, or workmen who have but little daylight work in the open air are extremely white, but far from anemic. The cheeks may be ever so pale, the hands white, but the lips and conjunctivæ fail to show lack of coloring matter in the blood. Without an accurate blood examination such individuals are frequently given iron for long periods of time, a proceeding which is certainly useless and often harmful.

One of the most striking cases of this sort presented itself at my dispensary at the University of Pennsylvania last winter—a man, aged 32, a carpenter, presented himself with symptoms of general weakness with some digestive disturbances, but without loss of flesh. His skin was extremely pale, but repeated examinations showed his hemoglobin to be 90 per cent., with a normal number of red corpuscles. Certainly any one, without most careful observation or without a blood-count, would have considered this man anemic and have uselessly given iron. The examination of his blood excluded any form of anemia.

The opposite condition of affairs is just as frequently present. A person may have at the time of examination a flushed face and give every indication, as far as the skin is concerned, of a normal blood-count, yet examination will show a decided reduction of the hemoglobin. An example of this condition presented itself in my office while this paper was in process of preparation. A girl of 17 was brought by Dr. Evans, of Philadelphia. She had been told a number of years ago, that she was likely to die of aneurysm of the arch of the aorta. She was extremely nervous, and presented all the symptoms of a neurasthenic. Physical examination at once disposed of the question of aneurysm. Her face was florid, unusually red for one who was ill; her lips, however, suggested that she might be lacking in some of her blood elements. Examination for hemoglobin showed only 65 per cent., notwithstanding her florid appearance.

Perhaps no class of patients are treated with less foresight or with less accuracy than are chlorotic girls. They present themselves to their physicians with symptoms such as these: dyspnea, palpitation of the heart, perhaps edema, or hemorrhage from some mucous membrane. Probably a slight cough accompanies the disorder, together with loss of appetite and rapidly increasing pallor. Time and again such individuals have presented themselves at our clinic with a diagnosis of tuberculosis or of heart disease. An accompanying bronchitis, or the rapidly beating heart with hemic murmurs have lent color to this diagnosis. An examination of the blood with the proper instruments, which is done very quickly, shows the hemoglobin to be from 20 to 50 per cent., with but little reduction in the number of red corpuscles. The physical signs then become explicable, and what was a hopeless case becomes one amenable to treatment. Such a mistake in diagnosis occurred in my own practice. In my first year I was called to see a girl of 16 years; she was pale, and had a general edema; her heart's action was tumultuous, and a loud systolic murmur was heard over the entire organ. I made a diagnosis of organic heart disease, but fortunately put the patient upon Blaud's pill. She rapidly improved, and is to-day a buxom woman of 30, perfectly well. A blood examination in this instance would certainly have shown me the error of my diagnosis; and would have saved the family much unnecessary worry; but I would not have had their unmerited praise, for so great is the faith of the family, because this patient was apparently cured of a fatal malady, that to this day they believe I permanently cured the patient of heart disease. Unfortunately for patients generally, no such happy ending occurs until a proper diagnosis is made, which can be reached by a blood examination alone.

In cases of chlorosis perhaps the most important use of blood examination is to determine when the patient is recovered. I have frequently seen cases of chlorosis which had all of the typical symptoms return after one or two weeks of proper treatment and declare themselves entirely well. True, all symptoms were much less, but a blood examination showed but little change in the hemoglobin or in the number of corpuscles. Doubtless many of the cases which have dragged on almost indefinitely in the hands of other physicians have done so because of the failure to be accurate, by carefully examining the degree of hemoglobin and the number of blood-cells in all cases before they are discharged. No case of chlorosis should be discharged until the hemoglobin reaches a degree of 80 or 85 per cent., and the corpuscles 4,000,000 to 5,000,000.

---

*Presented to the Section on Practice of Medicine, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

For years malaria has been made the scapegoat for all conditions of the character of which we may be uncertain. Every patient with an intermittent fever associated with malaise of uncertain origin—especially if such a patient resided in a malarial district—was said to be suffering from malaria. Malaria is to-day one of the few diseases that can be positively diagnosed. I believe that no case should be diagnosed as malaria unless the plasmodium malariæ has been found in the blood. Examinations for this organism need a microscope and the knowledge how to use it. Unfortunately the blood is not frequently submitted to this test. If this were done, beginning cases of tuberculosis and intermittent fevers in pneumonia would be much less frequently called malaria.

During the last winter the following case came under my care: A lad of 8 was suddenly seized at midnight with a chill, followed with temperature rising to 104. By noon the next day the temperature was normal. The next day at 1 p. m. there was a chill, followed again by a rise of temperature to 104, which declined to normal by midnight. This was repeated the third day. A careful examination of the blood showed the absence of the malarial organism and the presence of a moderate leucocytosis. By the fourth day an undoubted consolidation of the lung occurred and the case followed the ordinary course of pneumonia in childhood. Examination of the blood in this case absolutely excluded malaria and directed attention to the lungs, which gave no sign whatever until the fourth day.

In cases of anemia of obscure cause, frequently a simple examination of the blood with a microscope will make at least a suggestive diagnosis. Egregious errors in diagnosis of cases of leukemia and pernicious anemia may be made by a very simple view of the blood under the microscope, as exemplified in the following cases; I was requested to see a case which had been treated for two years, first for tuberculosis, and later for malaria, in the first instance, because of increasing pallor and loss of strength, in the latter, because of an enormously enlarged spleen. A simple microscopic slide of blood showed a large increase of the white cells; a later count showed 170,000 per c.c. It is true that neither of the diagnoses made in this case was justifiable, but they would never have been entertained had the gentlemen—both excellent and wise practitioners of medicine—cultivated the habit of examination of the blood in obscure cases.

Another case came to me at the University of Pennsylvania with a diagnosis of cancer of the stomach, made on account of rapid failure of strength with severe gastric symptoms, together with increasing pallor. Physical examination showed no signs which would warrant a diagnosis of malignant disease; and blood examination showed a decrease of the hemoglobin to 20 per cent., with a marked diminution of the red-cells to 900,000. A slide showed marked poikilocytosis, and later a stained specimen showed the marked histological characteristics of pernicious anemia. Here, too, a blood examination, not necessarily extensive, would have saved the patient the absolute hopelessness occasioned by a diagnosis of malignant disease, and the doctor an avoidable error. Widal's serum reaction is to-day practiced by nearly all; a combination of this test with that of examination of the blood for the malarial organism will serve to positively determine between typhoid and malaria, a combination of the two diseases, or neither.

It is known that a count of the leucocytes will frequently decide between a specific fever such as typhoid and some inflammatory condition. The following case is an example of this fact: Miss P. was seen in consultation, with the following symptoms: Four years ago the patient suffered with typhoid fever, and at that time the attending physician noticed disease of the mitral valve. Four weeks before I saw her, she was seized with an intermittent fever, with occasional severe chills followed by an exacerbation of the fever and exhausting sweats. Physical examination showed an enormously dilated heart as the result of a double mitral disease, with no other physical signs. The fever was intermittent in type with marked daily remissions, though a true intermittency did not exist. The fever was not typical of malaria, which was the diagnosis that had been made. Examination of the blood by the board of health showed Widal's serum test to be positive. On account of the previous undoubted attack of typhoid fever, however, this was of little value. Examination for the plasmodium, repeated, showed its absence, and proved the case not malarial. The blood-count showed 40 per cent. hemoglobin; 3,000,000 red cells and 20,000 white cells, a most important factor in connection with valvular disease of the heart, in determining the diagnosis of an ulcerative endocarditis. The diagnosis was confirmed by the subsequent behavior of the case.

It is a well-known fact that in certain cases where the physical signs in the lungs are delayed, an increasing leucocytosis will help to determine the case as one of pneumonia, much to the benefit of the patient and the comfort of the physician.

It will be seen that I have not referred to the staining of the blood and the invaluable and often absolutely necessary steps toward the full study of the case. I have avoided this because such steps need a special training and familiarity with methods not always practicable in everyday practice. But if the preliminary and frequently entirely satisfactory steps be taken, then almost invariably some one can be found who will complete the examinations. The apparatus to be used in this means of diagnosis which I advocate are a microscope, slides, coverslips, hemoglobinometer and hemocytometer.

By the use of a microscope and a slide of fresh blood, one may observe, 1, whether the leucocytes are largely increased in number; 2, whether the red cells form properly in rouleaux, and whether they are of odd shapes; 3, the presence or absence of malarial organism. The first two observations may be made with an ordinary 1/6 objective. The last requires a higher power, preferably an oil-immersion. I have constantly at hand a case containing the latter two instruments, together with diluents and a most necessary rubber bulb. It takes but a few minutes—fifteen—at a patient's home to get the blood properly. The counting and examination can be done at leisure at home. Then, too, there is no undue display of instruments in the presence of the patients. The fresh blood may be preserved for several hours by using oil of cedar run under the edge of the slide. The diluted blood in the tubes can be easily preserved by putting an ordinary gum band lengthwise about them.

In conclusion, let me insist that this most valuable diagnostic measure is practicable for the ordinary, everyday physician. It will enable him [illegible]id ma[illegible]rs in diagnosis. It will help him to take a deeper, more scientific interest in his cases.

DISCUSSION ON PAPERS OF DRS. CAMAC AND FUSSELL.

DR. WILLIAM OSLER, Baltimore—I have been for many years impressed with the value of the clinical laboratory and the small laboratory in the wards: we can not any longer do without either; they are really associated; they are as essential to the proper equipment of the hospital as the internes. They are to the physician just as the knife and scalpel are to the surgeon. I was glad that Dr. Camac referred particularly to the need of the clinical laboratory in the outdoor department of the dispensaries, for, after all, it is in the dispensaries that cases are most frequently not only diagnosed, but where they come for diagnosis. A very much larger number of patients would receive good treatment if they received proper diagnosis; and so I think the dispensary should have the aid of a small clinical laboratory. An interesting point is that the equipment need not be elaborate. A small equipment will suffice. An important and essential equipment is in the brain of the dispensary physician and his assistants.

I am particularly glad to hear Dr. Fussell and to see his bag. I would rather see his bag than see Dr. Fussell. The doctor can be seen at any time but not his bag. That is the sort of practitioner into whose hands I should like to fall if I had a case of ulcerative endocarditis; that is the sort of a man who not only has a microscope but knows how to use it. The average practitioner needs a microscope, needs it with him in his bag.

Therapeutics.

Lasting Anesthesia.

Lasting anesthesia can be produced by spraying ethyl chlorid over a surface previously moistened with a concentrated watery solution of cocain. Cocainized ethyl chlorid has been employed for opening abscesses, etc.—*Bardet: Med. Rec.*

Pruritus Senilis and Its Treatment.

Parisot, in the *Revue méd. de l'Est*, associates pruritus senilis with an autointoxication which has its origin in the intestinal tract and is accompanied by the incompetency of the kidneys present in old age. The blood is thus saturated with poisons, which produce a direct irritation of the nerve-terminals. In old age the liver, in an autotoxic sense, does insufficient work, the activity of the kidneys is diminished and, on account of retardation of digestion, the intestines always contain large quantities of fecal matter. The conclusion is that senile pruritus is a toxin-urodemia. The senile changes in the skin produce only a local pruritus, never a general condition. The treatment which the author recommends consists of benzoic acid, naphthol in daily doses of thirty grains, careful regulation of the bowels and a milk cure.—*Albany Medical Annals.*

Reflex Coughs of Children.

The editor of *Pediatrics*, referring to the two principal varieties, quotes MacCoy to the effect that hacking night-coughs of children are mostly due to nasopharyngeal obstruction, with mechanical irritation by retained secretions. The other class, a paroxysmal hacking cough, described by Dr. Francis Warner, of London, occurs in emaciated children with poor appetites, but who have a normal temperature and apparently healthy lungs, and is attributed by him not to peripheral irritations, as of intestinal worms, but to unbalanced central nerve-action. This opinion, somewhat at variance with that generally held by the profession at large, is based on the examination of 22,000 school children.

Acute Intestinal Catarrh.

Professor Ewald prescribes in obstinate acute intestinal catarrh:

℞. Resorcini ....gr. lxxv
Bismuthi salicylatis,
Tanningen, āā.......................... ʒss
Sodium carbonate.......................... ℥ii
M. ft. pul. Sig. Small teaspoonful every two hours.—*Georgia Med. and Surg. Jour.*

Urticaria.

Mr. Skinner, pharmacist to the Great Northern Hospital, recommends the following formula for allaying the itching, burning sensation of urticaria:

℞. Liquoris hammamelidis.......................... ℥ii
Salis maris .... ℥ss
Aq. dest.......................... Oi
M. Sig. To be applied freely.

He also speaks highly of the following cold cream:

℞. Adipis benzoinat .... ℥iv
Ceræ albæ .... ℥ss
Cetacei .... ʒi
Boracis .... ʒss
Glycerini .... ʒi
Aq. coloniensis..........................℥iiss
M.
—*Therapeutic Gazette.*

Migraine Accompanying Anemia.

℞. Ext. cannabis indicæ..........................gr. 1/6
Ac. arseniosi..........................gr. 1 1/60
Ferri pulv..........................gr. i
M. Ft. pil. No. I. Sig. One pill three times a day.
Or:
℞. Ext. cannabis indicæ..........................gr. 1/6
Pulv. digitalis..........................gr. ss
Ferri lactatis..........................gr. ii
M. ft. pil. No. i. Sig. One pill three times a day after meals.
—*Med. Standard.*

Inhalation of Balsam in Catarrh of Upper Air-Passages.

In laryngitis and catarrhal bronchitis, a few drops of the following mixture is to be placed in a caraffe-shaped bottle and heated gently over the flame of a spirit lamp. When the bulb becomes filled with the vapors they are drawn by the patient through the nose by means of a tube with a flaring end.

℞. Eucalyptol 25
Menthol 4
Terpinol 2
Essence of pine.......................... 07
M. For local use.—*Kafemann: Med. Rec.*

Instant Relief of After-Pains.

According to Winterburn (*Jour. of Obstetrics*), in many cases a nice warm meal is better than any medicine; "still, where the pains are exhaustingly severe, I turn to amyl nitrite. This potent drug is a very efficient controller of after-pains, and used cautiously, I see no reason to apprehend harm from it. A neat way of using it is to saturate a small piece of tissue paper with five or six drops, stuff this into a 2-dram vial and request the patient to draw the cork and inhale the odor when she feel the pains coming on. It acts with magical celerity."—*Med. Prog.*

Painful Dysmenorrhea.

The *Progrès Médical*, citing *Presse Médicale*, attributes the following to Dalché:

℞. Ergotin ....gr. 1½
Sulphate of quinin..........................gr. 30/100
Powdered digitalis leaves.......................... 15/100
Powdered coca, q. s.
M. For one pill. Sig. Three to five may be taken daily.—*N. Y. Med. Jour.*

Acute Coryza.

M. Sanger urges (*Therap. Monatschrift.*) the importance of adopting the right mode of administering topical agents in this complaint, e. g., medicated snuffs, vapors, etc. They should not be introduced into the nose by forced inspiration. Such forced inspiration increases the existing hyperemia of the nasal mucous membrane, and the swelling, hypersecretion and tendency to sneezing. *The best remedial agents are: turpentin, 2 to 5* per cent., alcoholic solution of menthol-camphor, with tannin, cocain and menthol. A mixture of equal parts of peroxid of hydrogen and water is recommended for use in spray. These remedial substances should be introduced into the nose by mechanical means—sprays, insufflators, etc. Hot aqueous vapor is also useful, and the writer has had excellent results with compressed air, introduced by means of a Politzer ball. In using the last, in order to protect the middle ear, the other nostril and the mouth must be kept open. Relief is also to be obtained by preventing nasal respirations by plugging the nose with cotton-wool. Diaphoresis is a rational means of combating the disease, and will often cut short the commencing attack. The writer considers the nasal douche as irrational. For the causal treatment he recommends quinin, salicylic acid, antipyrin and above all tolipyrin.—*Med. and Surg. Review of Reviews.*

Abortive Treatment of Erysipelas.

Dr. Labit (*Amer. Jour. of the Med. Sciences*) recommends the use of a 10 per cent. solution of iodol in collodion. The affected area is thoroughly painted, and the coat extended for an inch over the healthy skin. If upon the scalp, it is first shaved, then painted. That the iodin contained in the iodol is absorbed is shown by its appearance in the urine. Frequently within twenty-four hours all symptoms of the disease will disappear. It is not claimed that iodol is the only specific for the streptococcus of Fehleisen; doubtless other antiseptics can produce the same result. The pressure produced by the collodion, and its penetration, carrying with it the remedy into the tissues, are important. The method is not painful, but on the contrary, is anodyne.—*Mass. Med. Jour.*

Caffein Treatment of Heart Disease.

In the *Nord Médical*, M. G. Lemoine states that for fifteen years he has given caffein every day to patients suffering from myocarditis, and he feels certain that this treatment has prolonged their lives by avoiding the various discomforts, attacks of oppression, and temporary asystole to which they had formerly been subject.

M. Lemoine gives an account of a case in which, owing to the permanent and prolonged use of caffein, the patient enjoyed better health than she had for many years. The author refers to five similar cases, in the most recent of which this treatment has been employed for three years. One case was that of an emphysematous subject with cardiac degeneration, in whom this treatment had been instituted seven years ago, and, owing to the influence of the caffein, he had been enabled to resume his work.

M. Lemoine states that it is not necessary to employ large doses of caffein in order to obtain these results; on the contrary, he recommends weak doses, and as much as possible doses that vary more or less from day to day. This method has the great advantage of not accustoming the organism to the same dose always; consequently it is possible to continue the use of the drug without increasing the doses.

This method he considers the most logical, although, he says, it may be objected to, on the ground of accustoming the organism to a drug and of the physician's being obliged to gradually increase the doses until they become excessive. The author thinks, however, that he has answered this objection in presenting the facts themselves of the case referred to. He concludes that the caffein treatment is indicated in patients who suffer from cardiac weakness due to a disturbance of the pulmonary circulation. He states that he has employed this treatment with admirable results in emphysematous subjects with weak heart disease.—*N. Y. Med. Jour.*

Digitalis in Heart Trouble.

Dr. J. Groedel, in the *Practitioner* for April, says that cardiac insufficiency is an inevitable result of advancing heart changes. Compensation is established in most cases of valvular disease and may last for months or years, but if the patient lives there is sure to come a time in which heart failure is more or less pronounced. In those cases he recommends the combined administration of digitalis, and advises that we should not wait until signs of want of compensation develop, such as dropsy, anemia and tachycardia. He recommends that the digitalis be given in doses of from 8 to 10 grains, once each week.

At such wide intervals the drug has no cumulative effects, but during its administration the quantity of urine should be carefully determined, and if it is not augmented the drug should be withdrawn. In the great majority of cases the digitalis is well borne by the patient, and the charge which is made that the drug causes a loss of strength and increases the weakness of the patient is unfounded, these changes occurring as a result of the disease for which the drug is given, and not of the drug itself.

He is convinced that where fatty degeneration is markedly benefited by digitalis there is sometimes a subjective cure of these cases.—*Medical Summary.*

Chloral in Eclampsia.

Dr. E. Blanc considers the chloral treatment of eclampsia the most reliable, and has satisfied himself that it exercises a favorable action upon the inflamed and obstructed parenchyma of the kidneys. The only safe method of use is by the stomach or rectum. If the women is in a comatose condition it is, of course, impossible for her to swallow, and accordingly the rectal method is generally preferred, the chloral being emulsified by means of milk and the yolk of eggs.

Inasmuch as the enemata are usually expelled, Dr. Blanc prefers the method of Prof. Fochier, whereby an esophageal tube is introduced into the stomach and the chloral injected. If it is impossible to open the mouth, the tube may be passed through the rectal fossæ. The chloral solution should be made in the strength of 1/30 to 1/40. The dose should not exceed 45 to 60 grains. In this manner two to four drams of chloral may be administered in twenty-four hours. As the remedy appears to have a pathogenic action, it is well to give 45 to 60 grains a day in severe albuminuria of pregnancy. Its administration should be combined after the disappearance of the crisis for the purpose of eliminating toxic matters from the blood.—*Jour. de Méd. de Paris.*

Cacodylic Acid in Pulmonary Tuberculosis.

The Paris correspondent of the *Practitioner* (May, 1900, 552) describes cacodylic acid as a tasteless, almost odorless, organic compound of arsenic, containing a large percentage of this substance in soluble form, and being at the same time non-toxic and easily tolerated by the organism. It is a feeble acid, and not at all caustic. It has been employed successfully in the treatment of profound anemia, malaria, and tuberculosis. In cases of tuberculosis the drug is better given hypodermically, rather than by the mouth, in the form of sodium or potassium cacodylate, in doses not exceeding .10 gm. of cacodylic acid daily, the average being from .02 to .05 gm. The injection should be continued for seven or eight days, followed by a free interval of eight or ten days, after which the treatment should be resumed. Loss of appetite or elevation of temperature is an indication to cease the treatment, as also are signs of saturation, which is manifested by congestive flushings of the face or restlessness. Hyperalimentation should be practiced at the same time. The diet should preferably be rich in phosphorus and calcium, and may include fish, brain, milk, the yolk of egg, vegetables and bread. Phosphates with sirup or with glycerin should be interdicted. For the control of cough, hyoscyamus is preferable to opium. Exposure to dust should be avoided. A solution for hypodermic injection may be prepared as follows:

℞.	Acidi cacodylici	5	
	Sodii carbonat. q. s. ad saturationem.		
M.			
℞.	Cocain hydrochlorat....................		08
	Creosoti (dissolved in 8 gm. alcohol)....		33
	Aquæ destillatæ q.s. ad.................	100	
M.	Add cacodylic acid solution.		

Sig. .015 c.c. to .03 c.c. hypodermically.

One c.c. contains .05 gm. of cacodylic acid. The solution keeps well. The injections are painless, and unattended with danger, although, on the other hand, when administered by the gastro-intestinal tract, the solution is decomposed into a poisonous product, causing epigastric pain, loss of appetite, a sense of fatigue, and sometimes diarrhea with loss of weight; also diminution in the secretion of urine, which becomes albuminous. The drug is well borne by hypodermic injection, and neither tolerance nor habituation is established. Small doses of potassium iodid, from .1 to .15 gm. in the twenty-four hours, may be given at the same time.

Treatment of Tabes Dorsalis.

When tabes dorsalis develops subacutely, or when subacute exacerbations occur, Benedikt (*Wiener Med. Woch.*, 1900, No. 21, p. 1017) considers antiphlogistic treatment indicated, viz., absolute rest, applications of cold to the vertebral column, possibly the use of wet cups, and the internal administration of extract of ergot. At a later stage, when sclerosis of the posterior columns is advanced, afflux of blood to the parts must be favored, and this is best accomplished by means of an active Scottish douche. Electricity is an important therapeutic measure, especially central galvanization. Faradism is of subordinate value for the relief of secondary symptoms of anesthesia, and as a local sedative for the relief of local tabetic pains. Cold-water treatment has a similar value. Warm-water bathing may be injurious; it is without effect upon the morbid process. If it alleviates pain, it increases the difficulty in movement. Bloodless extension is useful, but the most important therapeutic measure consists in exposure and stretching of the sciatic nerve; motility is thereby improved, and pain is relieved. Massage of the nerves is of subordinate importance, while therapeutic exercises are capable of a limited amount of good. Mercurials and iodids are often administered without justification. Even when a history of syphilis can be obtained these remedies should be used with care. In such an event subcutaneous injections of mercurial chlorid may be given first. Should these not yield good results, better effects can not be expected from more active treatment. Should improvement occur, mercurial inunctions may be begun, the dose being cautiously increased from thirty to sixty grains. Should improvement become stationary, or should aggravation ensue, the treatment should be suspended. Daily doses of fifteen grains of iodid will generally be sufficient, and the effect should be carefully watched. Other remedies, such as silver nitrate and extract of physostigma, are of little importance. Sodium iodid, the salicylates, phenacetin, etc., may be employed as analgesics, but morphin is still the most potent remedy for this purpose. Cauterization also is useful, especially for the relief of gastric crises.

Treatment of Alcoholism.

At a recent meeting of the French Academy of Medicine, Crivelli (*The Lancet*, May 19, 1900. p. 1473) reported that in a large number of cases of alcoholism he had observed marked improvement and occasionally permanent cure as a result of the following method of treatment: Injections of artificial serum are made and followed by complete rest, baths, massage, light diet, and coffee. Then a solution of strychnin, 1 per cent., is administered hypodermically twice a day, commencing with three drops and increasing the dose by two drops daily until toxic symptoms appear. This generally happens when the dose has been raised to between twenty and forty drops, corresponding to .003 or .005 gm. of strychnin. The dose is then gradually reduced until it reaches two drops.

Mercurial Treatment of Lupus and Leprosy.

Ehlers, editor of the new international journal, *Lepra*, in a communication, urges the general adoption of Fournier's intermittent inunction method of mercurial treatment in leprosy, from which he anticipates brilliant results, as he has found it of great benefit in lupus. The results of mercurial treatment of leprosy in Iceland, Jamaica and in Haslund's experience have been extremely favorable. Ehlers' mercurial treatment of lupus was either injections of calomel or Robin's pills with the following formula:

℞. Sublimat. corros.
Natr. chlor.
Vin. thebaic., āā........................ 1
Mic. panis........................ 5
Gluten .... 2 } 5
Glycerin. 2-3
M. Ft. pilul. c. S. one to three pills a day, during meals.

How to Make a Mustard Plaster.

Never place a cold mustard plaster on a patient. The shock is like a sudden plunge into cold water. Before you commence to mix the paste be sure you have the necessary material at hand. First put a large plate where it can get warm, not hot. Then stir the mustard and flour thoroughly together before you add the water, which should be tepid; stir in enough water to make a paste about the consistency of French mustard. Place your cloth—an old handkerchief is best—on the warm plate, spreading the paste in the middle of it, leaving a margin wide enough to lap well over on all sides. Do not remove paste from the plate until ready to apply. Place a folded cloth between paste and patient's clothing.—*Ex.*

Medicolegal.

Where Non-Experts Can Not Testify on Insanity.—The Supreme Court of North Carolina makes the statement, in the case of Whitaker vs. Hamilton, that the rule, or rather exception, which was first adopted in the English courts, permitting any one whose acquaintance and means of observation of the party whose sanity is in dispute are sufficient to express his opinion as to his mental condition, has been received in all the states of the Union, except Massachusetts, Maine, New Hampshire and Texas.

Sufficient to Connect Death with Injury.—A man, in apparent good health and vigor, it is assumed by the appellate division, second department of the Supreme Court of New York, in Thurber vs. Commercial Travelers' Mutual Accident Association, receives an injury sufficient to cause death by deficient circulation, through weakening the action of the heart. Under treatment for a month he exhibits to skilled physicians the unmistakable conditions which tend to indicate the presence of this apprehended danger. Yet he starts unhealed upon a considerable journey. A few days later, he dies, without any other known cause or illness, and upon postmortem examination no cause of death is revealed excepting such as is necessarily and directly traceable to the injury itself, the evidence of which cause is distinctly visible. Surely these facts, when fortified by the opinions of medical experts, are amply sufficient, the court holds, to connect the death with the physical injury, and to supply a certainty of proof not always obtainable in cases of this character. The proof, unrefuted, it adds, establishes the injury received at the time of the accident as the sole and proximate cause of death.

On Artificial Limbs.—A man, 59 years of age, who was a carpenter by trade, but who had most of the time been engaged in mining, met with an accident, which necessitated the amputation of his left leg about three and one-half inches above the ankle-joint. A physician, who said that he knew the kind of work that was required of a carpenter and of a miner, was asked whether a man could perform the work of a miner with an artificial limb, such as this man had obtained, with as much safety and readiness as if he had his natural limbs. This was objected to. But the United States Circuit Court of Appeals declares, Southern Pacific Company vs. Hall, that it is unwilling to say that it was error to allow the physician to give his opinion as to what the effect of the fracture and amputation would be in regard to the man's capacity to perform manual labor. The conditions resulting from the use of an artificial limb, it thinks, may be said, to a certain extent, at least, to be more clearly within the knowledge of, and may be presumed to be better understood by, a physician, than it is by the common knowledge of men engaged in the ordinary affairs of life. The purchase of the artificial limb in question, the court further holds, was an expense incurred by reason of the result of the injury, for which, if properly alleged in his complaint, he being entitled to recover damages, would have been entitled to recover. But the limb, it holds, did not fall within the category of any expense which could be allowed under an averment as to general damages.

Value of Opinion Evidence.—Evidence which is made up of mere theory and speculation, and which suggests mere probabilities, an Iowa judge said, in the case of Brush vs. Smith, ought never to be allowed to overcome clear and well-established facts, and, he declared that, further, the law recognizes expert testimony as the lowest order of evidence. This statement was made at the conclusion of giving the jury the usual instruction with reference to the value of expert evidence in general. The Supreme Court of Iowa holds that it was error. No doubt, it says, evidence which consists merely of the opinions of witnesses should be received with caution, for it is well known that a witness testifying to an opinion is more likely to be mistaken than a witness who testifies to a fact.

But, while it is to be received with caution, it is not always true that it is of little value, or the lowest order of evidence. In some cases it may be of great value, and of the highest character. To partially illustrate: Here, two veterinarians had given evidence respecting the disease known as "hog cholera," and had testified that certain hogs were infected with it at the time they were sold to the plaintiff. Now the disease among animals denominated "cholera" is so well known and established, has been the subject of so much investigation by experts, and its symptoms and effects have become so well recognized by professional veterinarians, the court holds, that the evidence given in this case, based on proven facts, should not have been disparaged as it was by the language above condemned.

Consulting Physician for Priapism.—An applicant for life insurance being asked how long since he consulted a physician, the word "consulted," the United States Circuit Court of Appeals holds, does not relate to the opinion of a physician concerning a slight or temporary indisposition, speedily forgotten. Furthermore, the applicant having denied ever having had any disease or ailment, the court holds that, the physicians testifying on this point having each pronounced the applicant to have had a specific malady which the other did not discover, it was clearly a question for the jury whether each was not mistaken, and that no malady existed. On the other hand, the court holds, Hubbard vs. Mutual Reserve Fund Life Association, that where there is a question practically asking what "disease or ailment" any physician consulted discovered, the words "or ailment" broaden out the expression, and cover mere symptoms, so long as they are in themselves troublesome, as priapism is troublesome. In consequence, it does not consider that the fact that the physician describes priapism as only a symptom aids the case any more than it would for one to maintain that, though he had consulted a physician for a persistent and troublesome cough, lasting for years, it was not a disease, but only a symptom. To this it adds that, in the supposed case of such a cough, there would be an unquestioned concurrence that it was an "ailment," within the meaning of questions of this nature, and the same concurrence would exist with reference to priapism, if it were so well known as coughs.

No Excuse for Not Having License.—The defense to the Mississippi case of Bohn vs. Lowry, an action brought to recover for professional services, was that the plaintiff had not been examined and had not obtained the required license to practice in that state. At the trial, he testified that by profession he was a physician; that he had practiced medicine seven years; that he was a graduate of Tulane University, and of the Charity Hospital of New Orleans, La.; that he had applied for and received a temporary license from the Mississippi State Board of Health, and that he did not go before the board of examiners at the meeting held just prior to the expiration of such license because he was sick. But, even under such circumstances, the Supreme Court of Mississippi holds that he could not maintain an action for professional services without the license required by law. That he was a graduate of Tulane University, and a skilled physician, it says, was not to the purpose. That he was disabled by sickness from obtaining a permanent license, which, doubtless he would have done, if he had been before the board, was his misfortune. Looking back, it seems that it would have been a reasonable and wise provision of law that it should have authorized the board of health to extend a temporary license for inability to attend a meeting of the board on account of sickness or other adequate cause. But, after saying so much, the court adds, it is for the legislature to insert such provision, and not for the court to ingraft it.

Board of Health May Employ Inspectors.—The mere complaint of a nuisance, the appellate division, second department of the Supreme Court of New York says, in Kent vs. Village of North Tarrytown, will not have the effect of determining that a nuisance exists. Neither will a declaration of a board of health establish a given condition to be a nuisance, when in fact it is not so. Hence, when a board of health is required to execute the health laws, suppress nuisances, and to make rules and regulations therewith, the court holds that, in the execution of law, it is quite within its powers to make employment of persons when necessary to inspect, report and describe a given situation, in order that it may intelligently act thereon. Nor does it consider that because there may be statutory language giving it power to employ persons to carry into effect its rules and regulations, the power of employment is thereby necessarily limited to the right to employ after the nuisance has been declared. It holds that such language is broad enough in its scope, when taken in connection with the purposes and objects of the law, to authorize the employment of necessary persons in connection with the whole subject-matter, as well as for the duties which they are obligated to perform. However, where the board is authorized by statute to fix the compensation of an employee, the court does not think that has reference to the audit of a bill of an aggregate amount for services extending over a considerable period of time, but rather refers to a contemplated hiring for a specific period, and relates to the fixing of a per diem or other compensation, measured by the length of service and its character.

Locating City Pest-House in Rural Community.—Section 2568 of the Iowa Code provides that the mayor and council of each town or city, or the trustees of any township, shall constitute a local board of health within the limits of such town, cities or townships of which they are officers. The board, it then says, shall have power to make such regulations as are necessary for the protection of the public health respecting causes of sickness and quarantine, and to proclaim and establish quarantine against all infectious or contagious diseases dangerous to the public, and maintain and remove the same. This statute, the Supreme Court of Iowa says, in Warner vs. Stebbins, specially defines the territorial limits within which a local board of health may act. With the limits defined, it is by law made the guardian of public health, and it is its duty to stand as a wall between the inhabitants of the territory over which it has jurisdiction and dangerous contagious diseases. Beyond its prescribed boundaries it has no power or authority. The power given to local boards by this statute is broad. It is in the nature of legislative power delegated to the officers of a municipality for the preservation and promotion of the public health, and, while its use as an instrument of oppression by the local authorities will not be permitted, acts done thereunder, in good faith and for the purpose of promoting the general health, and for the purpose of preventing the spread of dangerous contagious diseases, will be upheld by the courts. Now this was an action brought by the board of health of one township to restrain a neighboring township board of health from establishing a pest-house on land purchased in the first mentioned township for hospital and other purposes by a city forming part of all said neighboring township. Moreover, section 880 of the Code provides that cities may acquire and hold ground outside of their municipal limits for cemetery and hospital purposes. But the supreme court does not think that this statute was intended to establish pest-houses in thickly-settled rural communities. The health regulations of the state are a part of its police powers, and, if their enforcement abridges private or corporate rights, it holds, such rights must yield to the general public good. So the conclusion of the court on the merits is that the defendants, acting as the board of health of the city township, had no power to establish a smallpox pest-house in the other township against the objection of the board of health of that township, and that an injunction would lie to restrain them from so doing. Section 2570 of the Code, which provides for the care of infected persons by the local authorities, the court does not consider enlarged, in any way, the territorial limits of their jurisdiction, nor authorized the transfer of the disease to the jurisdiction of another board of health. Indeed, it says that the members of the complaining board of health would, as such, have been remiss in their duty had they permitted smallpox patients to be domiciled within their jurisdiction, upon the theory that the disease might not spread. It maintains, too, that if a local board of health may quarantine a person within its territorial limits who is afflicted with a well-developed case of smallpox, the logical conclusion follows that it may restrain those who attempt to take him there, not because his presence there might constitute a nuis [illegible] t [illegible] he higher ground of public welfare and pub [illegible]

THE JOURNAL OF THE
AMERICAN MEDICAL ASSOCIATION.
61 MARKET STREET, - CHICAGO.

SATURDAY, JULY 28, 1900.

HEALING OF WOUNDS OF THE OVARY.

Various processes in the ovary of a progressive or constructive character have been described from time to time, but there has been no detailed account of the rôle enacted by the different histologic components in regeneration so extensive and thorough as the recent work of Maximow.[1] Lothrop studied the healing of wounds in the ovaries of rabbits and dogs made by excising small portions of the organs by crushing, and by passing ligatures through them; he not only failed to note any *changes in the germinal epithelium which covers the* ovary but also omitted to describe the multiplication of ova which he claimed took place. Sselsnew did not find any progressive changes in either the ova or the follicles after wounds, and both Phister and Levi have described changes entirely retrogressive in the inflammations produced experimentally in the ovaries of amphibia. Although it has been asserted that a compensatory hypertrophy of one ovary may follow the removal of the other, even this rests upon an insecure basis. Maximow studied wound healing in young and adult rabbits and in a few adult guinea-pigs, using between forty and fifty animals, and at periods of from five to eighty days after the wounds were made. The previous work of the same investigator upon the process of healing of wounds of the testicle[2] enables us to form some estimate of the degree of differentiation and the ability to proliferate of the various cells concerned in spermatogenesis; and it is self-evident that a knowledge of the methods by which wounds in the ovary heal is of greater value, since with the rupture of every mature Graafian follicle a wound is produced. The wounds in this study were made by single incisions, by needle puncture, by passing silk ligatures through the ovary and by excising small wedge-shaped pieces—naturally, all under strict precautions to prevent infection. It was learned that the external germinal epithelium begins to cover defects of the surface during the first twenty-four hours, in a manner analogous to the epidermization of wounds elsewhere The columnar and cuboidal cells at the borders of the wound become flattened and spread out; in this manner alone, surfaces of considerable extent may be covered anew. The cells also possess migratory powers, and on the second or third days after the wound, multiplication by karyokinesis is marked; they may so fuse with one another that a sheet-like or syncytial membrane is produced; they also may penetrate into the crevices of wounds. When extensive blood-clots or masses of necrotic tissue fill the wound, the regeneration of epithelium is hindered; but small masses of fibrin may be coated over with new epithelium. Regeneration of this epithelium ceases on the sixth or seventh day.

In the narration of the modifications which take place in the connective tissue of the ovary, there is a careful review of the facts which have so far come to light pertaining to the so-called "segmental cells," which are larger cells, twenty-four microns in their long diameter, with usually excentric nuclei, and cell bodies, which have a dense reticular structure. They often contain small globules of fat or other substance which blackens with osmic acid. The origin of these cells has been a much-mooted question. Maximow controverts the opinion of Harz, who traced their origin to the Wolffian tubules, with the fact that they are most numerous in adult ovaries. He not only accepts the view recently advanced by Rabl that they are derived from the cells of the *theca interna* of follicles which have undergone a physiologic shrinkage, but conceives it possible that they may emanate from connective-tissue cells of the ovary. In the necrosis of these large cells a substance is produced which exerts a remarkable positive chemotaxis for leucocytes; the leucocytes are found heaped up around and within them, and eventually the disintegrated stroma cells are entirely appropriated by the leucocytes or by other phagocytic cells. Although for the most part retrogressive changes were observed in the stroma cells, they may multiply by indirect mitosis or even form multinuclear "giant cells." No evidence was found of the direct participation of the stroma cells in the formation of the cicatrix.

By the incision of large follicles, the ovum escaping, a process of healing resulted which corresponds closely with the spontaneous development of corpora lutea. Wounds afford a point of entrance for granulation tissue. In small and immature follicles in the neighborhood of the wound, no progressive changes in the ovum were noticed.

As might be expected, in a discussion of the healing of wounds of mature Graafian follicles, and of corpora lutea, reference is made to the theories which prevail respecting the large "luteal cells." Maximow concurs with the views at present held by most investigators, namely that they are derived from the *theca interna.* Evidences of the multiplication of these cells were found only after the most painstaking search; only Rabl and Sabotta have observed mitosis of these cells. On the other hand, they exhibit many signs of degeneration. Wounds of corpora lutea healed promptly; injuries of the mature Graafian follicles were readily repaired by granulation tissue. Usually, however, the ovum escaped; in short, the formation of cicatrices in the ovary can be reasonably expected, providing infection does not occur.

The value of such work as this, and other work of like character, does not lie solely in the new knowledge brought to light; by excellence and careful attention to detail standards are formed which determine how investigations of this nature should be pursued.

LEUCOCYTES IN THE BLOOD IN TYPHOID FEVER.

It has become possible by means of modern methods of staining to demonstrate a series of changes in the blood of greater or lesser significance and diagnostic importance. The study of the physical and chemical properties of the blood is attended with such difficulties, and is so time-consuming, and its results, further, are of such a general character, that it can not be expected to be of distinctive value. The study of the morphology of the blood, especially of the colorless corpuscles, is, however, more feasible, and productive of better results, and there is reason to hope that a knowledge of the variations in the leucocytes may prove an important and trustworthy aid in diagnosis.

With the object of shedding light on one aspect of this subject, Naegeli[1] undertook a study of the blood in more than fifty cases of typhoid fever, making as many as from fifteen to twenty-five observations in the individual case. As a result, he concludes that examination of the blood, especially systematically continued enumeration of the varieties of leucocytes, constitutes one of the most valuable methods in the diagnosis and, to a certain extent, in the prognosis of typhoid fever. The variations in number of the neutrophiles, eosinophiles and lymphocytes are regular and pursue a definite specific course at the various stages of the disease. They are due to the action of the typhoid toxin upon the bone-marrow, the formation of neutrophile and eosinophile cells being inhibited; and probably, also to the influence upon the functions of the lymphatic structures, in consequence of which the number of lymphocytes is altered. The anatomic expression of the action of the toxin upon the bone-marrow is a definite pathologic result as exhibited in a marked preponderance of the myeloblasts and as marked a reduction in the neutrophile and eosinophile myelocytes. In the first stage of typhoid fever, when the temperature pursues an ascending curve, there is probably a neutrophile leucocytosis of moderate degree, which soon subsides and yields to a diminution in the neutrophile cells. The eosinophile cells disappear almost, if not wholly; the lymphocytes undergo moderate reduction. The second stage, with continued fever, is attended with further reduction in the neutrophile cells and the lymphocytes, although the latter frequently undergo increase toward the close. In the third stage, with remissions in temperature, the lymphocytes begin to undergo increase and their number may even now be considerable. The number of neutrophile cells becomes still less, and eosinophile cells begin to reappear at the end of this period. In adults the lymphocytes often remain still in small number. The fourth stage, with a declining temperature, is characterized by still further reduction in the neutrophiles, which now reach their minimum. The lymphocytes are generally still further increased, and are often more numerous than the neutrophile cells. The eosinophile cells increase slowly and regularly. In the first days after defervescence, the neutrophile cells begin to increase in number, the lymphocytes are quite numerous, and the eosinophile cells steadily increase in number. Some time after the termination of the disease, considerable lymphocytosis is encountered, with marked eosinophilia, and a normal or slightly increased number of neutrophile cells. This condition is less marked in adults than in children, and generally disappears in the course of a few months, while it persists a longer time in children. Also, during the course of the disease, all fluctuations in the leucocytes are more marked in children, particularly the increase in the lymphocytes. On the other hand, even in severe cases in children the figures do not fall so low as in adults, evidently in consequence of slighter injury to the bone-marrow and the lymphatic structures. Complications not of typhoid origin influence only the neutrophile cells, which, as a rule, increase in conjunction with suppuration, cystitis, parotitis, pleuritis, bronchopneumonia, nephritis, etc., but generally not to so marked an extent. An absence of leucocytosis in spite of complications, indicates the threatening condition of insufficiency of the bone-marrow, with inability to produce neutrophile cells.

In prognosis valuable guides are derived from the failure of the eosinophile cells to disappear, or their early appearance from the slight diminution in the neutrophile cells, and the marked increase of the lymphocytes, in a favorable direction; and from the marked diminution in all varieties and absence of leucocytosis in association with complications, in an unfavorable direction. Relapses are attended in all particulars with the same conditions as the primary disorder. The earlier views as to the fluctuations in the leucocytes in cases of typhoid fever—unequal division, absence of exudation, influence of splenic enlargement, positive and negative chemotaxis, etc.—are to be replaced by the assumption of the action of a toxin upon the bone-marrow and the lymphatic apparatus in the sense of an inhibition of function.

THE NEW YORK STATE MEDICAL ASSOCIATION.

The long struggle for supremacy between the New York State Medical Society and the New York State Medical Association has at last terminated in favor of the latter, which is the accredited representative of the American Medical Association, and it is now hoped that there will soon be a union of the medical profession in that commonwealth. The special charter recently granted by the legislature, followed by the decision of Justice McAdam, of the Supreme Court, that the Association, as the accredited state representative of the American Medical Association, has the right to legally represent the profession of that state, places the State Medical Association at the head of medical organizations as the representative of the medical profession in that locality.

As published in our news columns [illegible] the question raised [illegible] Asso ecute and collect fines imposed upon illegal practitioners of medicine, and the attorney of the New York State Medical Association made a test case for the purpose of determining the legal standing of the Association by a decision of the court. It is exceedingly unfortunate that the old state society has been placed in its present position, and the physicians of other sections regret that such a condition exists, but the few who dictated the policy that brought it about should shoulder the blame and be the first to return to lift those who have followed their advice up to the plan of organization promulgated by the State Association. This, if carried out, is bound to make the profession felt as a unit in advancing the interests of the public and in demanding the recognition of the rights of the physician and surgeon.

---

[1] Deutsches Archiv für Klinische Medicin, 67. B., 3, u. 4, H., p. 279.

The time is ripe for a thorough organization of the profession of the whole country, but before this can be perfectly done each state must have an individual, not a two-headed organization. There can not be two state societies in New York affiliated with the American Medical Association any more than in any other state. It is believed that the continued rapid growth of the New York State Medical Association, added to its new plan of organization, will soon result in ending the unhappy and unsatisfactory conditions of the past. The old bitter feeling is practically at an end, and a desire for a coming together is evident on both sides. A united profession in the Empire State will be a power for good, not only to the local profession, but to that of the whole country. It may be necessary for each side to make some sacrifice, to give a little here and take a little there, before a final union will be brought about, but, with few exceptions, all on each side are ready for this.

THE MEDICAL ASPECT OF THE CHINESE TROUBLE.

Now that it seems probable that the United States has before it, as a portion of its "white man's burden," serious and possibly prolonged and extensive military operations in China, it is well to face openly some of the sanitary problems it involves. China is by no means a healthy country; over a large part of its extent it supports a dense population, who live in conditions of hardly calculable unwholesomeness, and by their methods of agriculture, thrifty and thorough, but unsanitary, keep their land in a state of a midden heap. The water-courses are practically open sewers. Human life is comparatively cheap in China, and it is probable that the mortality rates of their cities and country districts from gastrointestinal disorders would be found higher than in most other countries, had we any reliable statistics. This is taking into account, also, the immunity they must have acquired during centuries of such conditions, and their tea-drinking habits, saving them perhaps from many of the perils of contaminated water. Our experience in the late war with Spain, and that of the British just now in South Africa, are enough to show us that there is no more serious peril to an army than this class of disorders, even under comparatively favorable conditions. What the sanitary problems of the medical staff in China will be, with the state of affairs that exist there, is a rather appalling question.

That the authorities are wide awake to the needs is shown by the precautions already taken, but not all the exigencies or possibilities of a campaign can be provided for, even with the best of foresight and care. If the war in China is to be prolonged over any considerable period of time there is no telling what medical problems will arise. The Chinese themselves may not prove an altogether contemptible enemy, even against the world, but whatever fighting injuries they can inflict seem to us to afford a far less serious prospect ahead than do the possibilities of army disease if the conflict is to be to any extent a protracted one, and our army has to be long on China's soil. If the troubles are to extend and involve the southern provinces of the empire there will be still other factors of disease to provide for than those mentioned. It is to be hoped that there will always be an intelligent co-operation between the military and the medical authorities, and that some of the mistakes made during our war with Spain will not be repeated. Matters are likely to be bad enough at the best, but any inconsiderate disregard of health needs by high military authority would make them incalculably worse.

QUACKERY IN FRANCE.

The bone-setters, magnetizers and the like that infest American civilization are making trouble also elsewhere. It is said that there is in France a regular school of magnetizer-masseurs that sends out its diplomated graduates to prey upon the public. This would not be a startling idea here, but one has had the notion heretofore that they manage these things better in France and that quackery had not so free a hand there. It is said, moreover, that the courts, with the same tendency of the legal mind that makes some of our jurists propagandists of Eddyism and lobbyists for osteopathy, show a tendency to recognize these frauds as legitimate medical practitioners. We have troubles of our own, but they make us none the less sympathetic with our French confrères.

THE NEW YORK MEDICAL JOURNAL.

Owing to the financial trouble of D. Appleton & Co., the *New York Medical Journal* has been sold, the new owner being Mr. A. R. Elliott, owner and publisher of the *American Druggist*, who conducts an advertising agency in New York. We are glad to note that Dr. Frank P. Foster, its efficient editor, has been retained. The *New York Medical Journal* is one of the old reliable journals of this country, has always been ably edited, and is recognized as one of the leading medical weeklies. It was started as a monthly in April, 1865, with Dr. William A. Hammond as editor. In 1871, the late Dr. Wm. T. Lusk and Dr. Jas. B. Hunter assumed the editorial management, these being succeeded by Dr. Frank P. Foster, in 1880, who has edited it since. In January, 1883, the journal was changed from a monthly to a weekly. D. Appleton & Co. became the publishers in 1868.

CHICAGO DIPLOMA MILLS.

The Chicago diploma mills that have by various names eluded the justice that the State Board of Health has sought to deal to them seem likely to be at last brought to book or at least seriously crippled in their future operations. Heretofore when legally suppressed under one name they could start again under another, since articles of incorporation were cheap and easy to secure in Illinois. Now, since Uncle Sam has taken a hand, as has been noticed in our news columns, the better part of their business, the advertising and correspondence portion, is cut off and bids fair moreover to bring serious trouble upon their operators. It is quite interesting to read the comments of the daily press upon this as compared to its stand when President Rogers tried to induce the last legislature to pass an act regulating the degree-giving powers of chartered institutions. Now it appreciates the discredit that the laxness of the laws has brought upon the city and state. Then it went spasmodically virtuous in behalf of the poor but worthy institutions that should not have their degree-conferring rights taken away by a grasping president of a highly-endowed university. Had Dr. Rogers' bill prevailed there would have been a few less small medical and other colleges in Illinois with the rights to give degrees, but there would not have been a continuation of the diploma-mill disgrace that has made Illinois degrees disreputable throughout the world. We are fortunate that our federal criminal code makes a crime of using the mails for purposes of fraud, but we should also have state laws strict and efficient enough to prevent it.

THE GLAMOUR OF THE ULTRA-SCIENTIFIC.

Dr. Patrick, in his Chairman's Address, published in this issue of THE JOURNAL, alludes to the charges that the neurologic specialists are practically therapeutic nihilists, and offers some figures that apparently point that way. In examining the issues for a year of four leading neurologic journals, he found that out of 199 original papers only three were on treatment, and out of 1033 abstracts only 74. In two years of two other high-class journals he found only one out of 115 original papers on a therapeutic subject, that is, he says, only 2.2 per cent. of the original contributions related to the cure or alleviation of disease. While his calculations are not altogether accurate, the figure is certainly a small one and if we are to accept it as indicating a tendency on the part of the neurologists especially, the showing would justify the charge. It ignores, however, the fact that treatment is not altogether neglected in articles in which it is not the leading theme. However, the neurologists have not been the only sinners in this respect, for the tendency to magnify the ultrascientific as contrasted with the merely practical is, so far as it exists, a common one in all the departments of medicine. There is a tendency on the part of some to be led off from equally important matters by the more showy, in a scientific point of view, results of pathology and clinical diagnosis. The tendency to minute observations seems, in a sort of way and to a certain extent, hostile to that broader view that covers the whole field, it may be said, more superficially, but in some ways more advantageously. We are apt to be captivated by the brass and glass of the laboratory and forget that it is just as important to know how to cure as to know how to diagnose a disease. The glamour of the ultrascientific is not confined to medicine alone, for almost the last public utterances of one of the greatest of American naturalists deprecated its existence amongst his fellow workers. It is well from time to time to have our attention called to such possible tendencies. The widening of medical science should not lead us to confine ourselves too exclusively to limited departments or let us fall into ruts. Medicine is a broad subject, but it is all the more necessary that its followers should be broad in their scope and not encourage too much their limitations by too exclusive attention to narrow fields.

PNEUMOTHORAX WITHOUT EFFUSION IN THE ABSENCE OF OTHER DISEASES.

The presence of air in the pleural cavity is known as pneumothorax, but it is only rarely that air is present alone, inasmuch as the causative factors are almost always irritating, if not actually septic; thus effusion also generally results, often serous and sometimes purulent, and the condition then becomes one of hydropneumothorax or pyopneumothorax. Air may gain entrance into the pleural cavity as the result of perforating wounds of the chest, perforation of the pleura through the diaphragm or the esophagus, or perforation of the lung. The last-named variety of perforation may occur in the normal lung from the rupture of air-vesicles, or as a result of local disease of the lung, and, also, in consequence of destructive or ulcerative disease of the pleura. Finally, pneumothorax may result from the generation of gas in the pleural cavity by the bacillus aerogenes. One of those rare instances in which the disorder appears in an apparently healthy individual, and is attended with effusion, was reported by F. Parkes Webber (*British Medical Journal,* May 19, p. 1224) at a recent meeting of the Clinical Society of London. The patient was a piano-fitter, 31 years old, with no previous history of pleurisy, hemoptysis, or pulmonary disease, and with no family history of pulmonary tuberculosis. Without violent strain or excitement, while at work, he was suddenly seized with pain on the left side of the chest, as if stabbed with a knife. Breathing gradually became embarrassed, and the pain was greatly increased by attempts at walking. When seen, a short time later, the respirations were about 30 and the pulse about 65. The movement of the chest was equal on the two sides, but no cardiac impulse could be felt. The area of cardiac dulness was displaced to the right of the sternum, and there were distinct signs of pneumothorax on the left side. When the patient was kept quiet in bed, the dyspnea and severe pain in the chest rapidly subsided. No splashing sound nor metallic tinkling was heard, and the signs of pneumothorax gradually disappeared in the course of thirty-two days. The first evidence of partial return to the natural condition was afforded by the absence of the bell-sound from the upper anterior portion of the affected side of the chest while the most persistent of the abnormal signs was the displacement of the heart. In the process of recovery from the pneumothorax the patient did not appear in any very ill. There was never any expectoration, nor sign of pleurisy or pleuritic effusion of serum, blood or pus. It is pointed out that this case and others like it, including the rare instances of recurring pneumothorax, can be best explained on the supposition that a subserous emphysematous bulla has burst, or that a minute tuberculous nodule has broken down and established a communication between the air-passages and the pleural cavity.

CONGENITAL WORD-BLINDNESS.

The mechanism by which expression is given to thought is most complex, and the modes in which the defects thereof comprehended in the designation "aphasia" may arise are correspondingly varied. The faculty of articulate speech bespeaks an accumulation of sound-memories, and that of written or printed speech an accumulation of visual memories as well. In addition, the motor mechanism of speech must in each instance be intact. A lesion of the auditory center in the first temporal convolution of the left cerebral hemisphere may give rise to total inability to appreciate the significance of sound—mind deafness, while a more circumscribed lesion will be attended with inability to understand or to repeat spoken language and with inability to read and to write from dictation, while the power of voluntary speech and writing, and of writing by transcript, is preserved, although words may be improperly used—paraphasia. This condition is known as word-deafness. Sounds are heard, but are not properly appreciated, although sound-memories can be revived. Lesions of the visual area in the postero-inferior portion of the parietal cortex on the left side may prevent conceptions of visual impressions, a condition that is known as mind-blindness; while the defect resulting from less extensive lesions, that cause only loss of the visual appreciation of written or printed language, is known as word-blindness. Aphasia has rarely been observed as a congenital condition, and Henshelwood reports two cases under his own observation exhibiting congenital word-blindness, as well as two others recorded in the literature. In all of these four cases, while there was no impairment of vision proper or of general intelligence, there was difficulty in recognizing by the sense of sight the letters of the alphabet, and especially words, although figures occasioned no difficulty. The disorder is believed to be due to some congenital defect in the center for the visual memory for words and letters. It is pointed out that the faculty of reading comprises two stages: one in which the individual letters of the alphabet are stored up in the visual memory through the intermediation of the auditory faculties, and another in which visual memory of words is gradually acquired and stored up. These visual memories of letters and words are supposed to be registered in the angular and supramarginal gyri of the left cerebral hemisphere in right-handed persons, and any abnormality within this area, from disease, injury at birth, or defective development, would be attended with great difficulty in learning to read. It is pointed out, finally, that similar instances may be by no means so rare as the absence of recorded cases would lead one to infer, as they may be commonly overlooked. The importance of their early recognition must be obvious, as much can be accomplished by patient and persistent training.

THE ACTION OF CELLULAR POISONS (CYTOTOXINS) OF ANIMAL ORIGIN.

One of the latest developments in pathology is the discovery and study of cytotoxins of animal origin produced by the injection of an animal with the various cells of another animal of a different species. The serum of the first animal gradually becomes toxic for the corresponding cells of the second animal. In this way there have been produced hemotoxins—substances that destroy red blood-corpuscles—leucotoxins—substances destructive of leucocytes—spermotoxins, destructive of spermatozoa, etc. Some reference has been made in these columns to these cytotoxic serums and their actions[1]. The fertile Metchnikoff sees in these demonstrations a number of far-reaching possibilities, and has busied himself in working out their application to human pathology and therapy. The success of serum treatment in diphtheria serves as an encouragement to work of this kind. This is the day of serums and of ferments, and everywhere investigators are engaged in preparing serums for the treatment of diseases of known as well as of unknown etiology. Returning to cytotoxins, Cantacuzène[2] has shown that the injection of small doses of hemotoxic serum has the paradoxic effect of greatly stimulating hematopoiesis, the red corpuscles of the rabbit mounting up to 9,000,000 per cubic mm., and hemoglobin reaching a value of 110; and Besredka[3] demonstrates that in small but repeated doses leucocytic serum causes a marked hyperleucocytosis. Metchnikoff, in conjunction with Besredka, reports an investigation of the action of serums of this kind in leprosy. For some time leprologists have been interested in the treatment of leprosy with the serum of Carrasquilla, prepared by injecting large animals with the plasma of the blood of lepers, and Laverde, produced by similar means, including the injection of the extract of leprous proliferations. Good results, but no full cures, have been obtained with serums of this character. Metchnikoff injected goats with defibrinated human blood; the serum of the goat soon acquired the power of dissolving the red blood-corpuscles of human blood. Two lepers were treated with injections in small quantities of the hemotoxic goat serum. Considerable improvement in the local lesions took place; about some of the nodules congestion and suppuration appeared, succeeded by cicatrization; the number of red blood-corpuscles increased unmistakably, also the quantity of hemoglobin. The local suppuration is explained as due to the increased number of phagocytic leucocytes produced by the leucotoxin present in the serum, and all the good effects are explained on the score demonstrated by Cantacuzène and Besredka to follow small doses of hemotoxins and leucotoxins. Besides, the action of the antileprous serums of the kind mentioned is to be ascribed to the presence of cytotoxins rather than to specific antibacillary substances. The general conclusion to be drawn from these novel experiments is that feeble doses of cytotoxins produce an increased activity of the corresponding cells. How far serum, containing hemotoxic and leucotoxic substances, may prove bene-

ficial in other conditions, accompanied with anemia, awaits further study.

Medical News.

PROFESSOR TOLDT has been elected dean of the medical faculty of the University of Vienna.

KNIGHTHOOD has been conferred upon Drs. Hector Cameron, Glasgow, and G. Hare Philipson, Newcastle-on-Tyne.

THE MONUMENT to Lavoisier, the distinguished chemist, in Place de la Madeleine, Paris, was inaugurated by the Minister of Public Instruction, July 27.

THE MAHARAJAH of Gwalior has offered the Government of India for service in China a fully-equipped hospital ship, upon which he proposes to spend twenty lakhs of rupees, or more than half a million dollars.

RUSSIAN ARMY SURGEONS to the number of 180 passed through St. Petersburg on their way to Khabarovsk to join the forces proceeding to the front. Several strong Red Cross corps are soon to be sent to China via Moscow. At present 400 ambulances are in operation with Russian troops in the field.

THE NATIONAL Red Cross Association met in Washington, D. C., July 10, and reorganized under the act of incorporation granted at the last session of Congress. The old association passed out of existence and a new advisory board was chosen, consisting of fifteen members, five elected for three years, five for two years and five for one year. Miss Clara Barton was chosen president.

LEGAL proceedings have been instituted by the authorities against the assailant of Professor Pozzi, as the French penal code provides protection for magistrates in the exercise of their functions, and Pozzi's official course in the *Haute Cour* and the Senate was the cause of the attack. He has made every effort to have the matter dropped and prevent the expulsion of Dr. Devillers from the Medical Club, where the incident occurred which led to the famous duel.

Professor S. Pozzi, Senator, President of the Club Médical de Paris. (From the Gazette Médicale de Paris.)

THE TRANSPORTS *Grant* and *Sumner*, now on their way to China, carry twenty-five trained female nurses, a part of the thirty recently requested for service in the reserve hospitals in the Philippine Islands. It is thought that some of these nurses will be ordered for duty on shipboard in Chinese waters. There are now in service nearly 200 female nurses, who are doing excellent work in the reserve hospitals in the Philippines.

TUBERCULOSIS IN PARIS.—Nearly 26 per cent. of the deaths in Paris in 1899 were due to tuberculosis—12,314 out of a total mortality of 46,988. The percentage of tuberculosis mortality at various ages was as follows: 1 to 20, 37.2; 20 to 40, 60.2; 40 to 60, 30.5, and over 60, 3.3.

RECIPROCITY IN NEW JERSEY.—The State Board of Medical Examiners of New Jersey, on July 5, 1900, adopted the following resolution: "Resolved that this Board will indorse the license of any State Board of Medical Examiners in the United States, in lieu of an examination; provided, first, that the candidates for indorsement shall present satisfactory evidence of having the academic and medical education required by this Board, and that the license presented for indorsement shall have been issued after a State examination of the same grade and kind as that required by this Board.

PENNSYLVANIA.

DR. HORACE HEYSHAM succeeds Dr. J. E. Eisenberg in the Charity Hospital at Norristown.

DR. BERIAH EDWIN MOSSMAN, JR., Greenville, has received the appointment of resident physician in the Allegheny General Hospital.

THE DAIRY and Food Department announces that during June there were 119 suits brought against violators of the oleomargarin laws, resulting in fines amounting to over $1800.

SUSPECTED CASE OF LEPROSY.

The town of Olyphant is considerably exercised over a suspicious case of leprosy. Soo Kee, a Chinese laundryman, had for some time been suffering with a disease of the skin, and as it was suspected of being leprosy his laundry was closed. From the fear that the Board of Health would place him in quarantine the man packed up his belongings and left town.

Philadelphia.

DR. GEORGE E. DE SCHWEINITZ has gone to Europe.

DR. B. FRANKLIN STAHL will spend the summer at Rangely Lake, Me.

DR. EUGENE LANE VANSANT will be in attendance at the International Medical Congress at Paris.

DR. E. E. MONTGOMERY will sail at an early date for Paris, to attend the International Medical Congress.

DR. MELVIN M. FRANKLIN has been appointed a surgeon on the staff of St. Joseph Hospital, to fill the vacancy made by the resignation of Dr. John S. Miller.

THROUGH the bequest of Mary Rose Smith, $5000 has been given the Episcopal Hospital for the purpose of endowing a free bed.

THE PRIZE of $100 offered annually by Dr. John B. Deaver for the best report of the surgical clinics at the German Hospital has been awarded equally to Dr. A. G. Ellis and Dr. H. F. Godfrey. An extra prize was given Dr. Cooley.

THE CHILDREN'S Country Week Association is using every means to dispatch the children of the slums to the country as fast as possible during the hot weather. One day of the past week, 341 children and 71 mothers were sent to different outlying districts.

THE EXTREME heat which has prevailed here for the past ten days shows no signs of abatement. During the week, there have been upward of 150 prostrations and a large number of deaths from this cause. The same condition seems to prevail throughout the entire state.

MORTALITY [illegible]TISTI[illegible]

The number of deaths occ[illegible] during th[illegible] ended July 21, was 564; [illegible] that week. The principal causes of death were: apoplexy, 13; cancer, 17: cholera infantum. 89; tuberculosis, 45; heart disease, 27; inflammation of stomach and bowels, 42; sunstroke, 17; diphtheria, 9; scarlet fever, 2; typhoid fever, 5.

PHILADELPHIA HOSPITAL.

Dr. C. S. Gans has been appointed on the staff to succeed Dr. J. Abbott Cantrell, resigned. Dr. M. B. Hartzell was also elected a member of the corps. Dr. Ella M. Anderson was elected assistant physician to the department for the insane. The number of patients in the hospital was 3684, an increase of 95 over the corresponding period of last year.

SANITARY ASSOCIATION.

This association from June 7 to July 14 admitted 83,319 persons, an average of 2653 for each working day. The number comprised 10,990 adults, 9179 infants: 53,765 children from 2 to 10 years of age, and 11,385 over 10 years. Last summer 166,554 women and children were taken to and from the sanitarium on the daily trips made by the steamers.

BEULAH ORPHANAGE.

Since the discovery of the first "baby farm" in this city, the police seem to exert more diligence in looking after others which have been reported. In the latest one, called the "Beulah Orphanage," a child died some time ago under rather peculiar circumstances. The coroner therefore ordered an investigation, and learned that the "orphanage" was under the charge of two men, and that the child died without medical attention. On inquiring the reason for this, it was said that the plan was the "*trust in God treatment*," or *faith cure*. On being asked as to who first suggested the place, the answer was "The Lord by His Spirit." As to why the child had died without a physician having been called, the reply was "Our Faith in God Kept Us." The coroner told the men they could send for a lawyer, which children have been entrusted to the care of the Society for the Protection of Children from Cruelty.

MARYLAND.

NEW ASYLUM AT SYKESVILLE.

A large number of patients from the overcrowded wards of Springgrove Asylum were removed, July 19, to the new cottages at Springfield Asylum at Sykesville. The new buildings are intended exclusively for women, and are one mile distant from the male department. No men are allowed near, and there is entire absence of restraint, the patients going about at will. Bathrooms, bedrooms, diningrooms and lounging-rooms are furnished almost luxuriously. The patients are encouraged to work, and while there is no compulsion, 85 per cent. of the male patients work willingly, either on the farm or in the industrial school. Mr. W. W. Spence, of Baltimore, has presented to the institution a handsome pool-table and equipment. The Waring system of sewerage has been put in, and all the buildings are connected by telephone. The crops are excellent, and 400 tons of ice are stored away, having been gathered by the inmates last winter.

Baltimore.

Dr. H. Burton Stevenson has been appointed demonstrator of obstetrics at the Baltimore Medical College.

The members of the Baltimore County Medical Association enjoyed an outing at Tolchester, July 19.

A boy, aged 14, died July 12, whose death is attributed to his having swallowed some of the water of Jones' Falls, a foul stream that traverses the city. He took a bath on July 4 and became ill the following day. There occurred symptoms of typhoid fever, delirium, and "dark spots all over his body." It is said that similar cases have previously been noted in this city.

NEW OFFICERS OF THE MEDICAL JOURNAL.

At a meeting of the *Medical Journal* company, held recently, the following officers were elected: president, E. J. Farber; vice-president, Dr. R. T. Wilson; secretary and treasurer, Dr. H. M. Simmons; Dr. John Fulton is editor-in-chief. The remaining directors are Drs. William Osler, John D. Blake, Wilmer Brinton and Hiram Woods.

MARYLAND MEDICAL COLLEGE.

This college, established about three years ago, will shortly erect a new hospital building to cost $25,000. The following appointments have recently been made in the faculty of the college: , Dr. Harry Gross, elected to chair of operative and clinical surgery; Dr. Ernest E. Quandt, elected to the chair of chemistry and toxicology.

MORTALITY STATISTICS

The death-rate for the week ending July 14 rose to 318, 171 being under 5 years of age. The death-rate was 30.47 per 1000. The following show the effects of high temperature: Cholera infantum, 99; diseases of infancy, 35; dysentery, 9; sunstroke, 7; senile debility, 13. The last figure shows how fatal to the old are spells of very high temperature. It is rather remarkable that there should have been 14 deaths from pneumonia and 22 from consumption.

A MEDICAL IMPOSTOR.

A man claiming to be "Dr. Charles A. von Ahlefeldt, of the Staff of Surgeons in the Navy of Germany," has been victimizing the Stafford Hotel and some of the profession here. He occupied the best room and entertained freely. He went to the Hopkins Hospital in a hack, presented his card, and being a good talker, with polished manners, and representing himself as a German surgeon on his vacation, he soon ingratiated himself there and had the Hopkins surgeons repeatedly to dine with him. When the bills were presented he disappeared, leaving an indebtedness of $238. He appeared to be about 40 years of age, had a military bearing and was faultlessly dressed.

ILLINOIS.

STATE BOARD OF CHARITIES.

The quarterly bulletin of the state commissioners of public charities shows that the number of inmates of the several eleemosynary institutions at the beginning of the quarter was 10,220; at the close, 9251. The northern insane hospital had 1102 inmates; the eastern, 2248; the western, 661; the southern, 1097; the central, 1440; the charitable eye and ear infirmary, 356; the asylum for feeble-minded, 830; for the blind, 251, and for the deaf and dumb, 511.

Chicago.

Dr. Sarah Hackett Stevenson sailed for Europe on the *St. Louis*, July 25.

Drs. D. W. Graham and **W. T. Montgomery** have just returned from a six months' trip abroad.

By the will of Timothy B. Blackstone, five institutions have received $25,000 each. Among them are St. Luke's Hospital and Passavant Memorial Hospital.

Dr. Edwin Klebs, professor of pathology in Rush Medical College and director of the laboratory in the Post-Graduate Medical School, has resigned, and after a few months spent in Switzerland, will locate in Germany.

Dr. Nicholas Senn's article on "The Humane Side of Warfare," which appeared in The Journal, March 31, has been reproduced in full "by special request" in the *Indian Medical Record, Calcutta*, of June 13.

A crusade against unsanitary rag and junk shops has been started. The chief sanitary officer has placed most of his force on this work and will compel every owner of this class of shops to comply with the health regulations. It is said that at present many of the rag-dealers are so anxious for business that they purchase rags which they know to be unsafe.

HEALTH DEPARTMENT.

The report of sickness and mortality for the week ended July 21 is very satisfactory, considering the various changes in temperature, humidity, etc., during that period. The death-rate per thousand was 12.78, which is a marked improvement on that for the corresponding week of 1899, which was 17.27. The total deaths from all causes were 454, 263 males and 191 females; 136 who died were under one year of age; 53 between 1 and 5 years, and 64 over 60 years. The principal causes of death were: acute intestinal diseases, 100; Bright's disease, 17; bronchitis, 11; consumption, 45; cancer, 21; diphtheria, 11; heart disease, 29; nervous diseases, 52; pneumonia, 15; suicide, 4; violence aside from suicide, 26; and sunstroke 15. During the twenty years from 1880 till 1899 the death-rate of the city has progressively decreased, as follows: 1880-1884, 12,319 deaths, 21.9 per thousand mortality; 1885-1889, 14,860 deaths, 19.2 per thousand mortality; 1890-1894, 25,363 deaths, 17.9 per thousand mortality; 1895-1899, 33,515 deaths, 14.2 per thousand mortality. The decrease has been marked as regards infant mortality. In 1880-1884 the deaths under 5 years of age were 52.2 per cent. of the total; in 1885-1889 this percentage was reduced to 48.7; in 1890-1894, to 45.5, and in 1895-1899 to 38.8.

Thirty-four cases of diphtheria were reported during the week, 34 of scarlet fever, and 2 of measles. There were 466 samples of milk and cream analyzed in the laboratory, 6 per cent. of which were found below grade. No new cases of smallpox have been discovered. Twelve individuals who had been exposed to contagion from the case last reported, and who had not been previously vaccinated, were vaccinated, and in each case typical primary results followed.

KENTUCKY.

Louisville.

GRAY STREET INFIRMARY.

THE GRAY STREET Infirmary will enlarge its building considerably, and will construct a modern private operating-room.

DR. THOMAS S. BULLOCK, because of pulmonary trouble, has been compelled to remove from Louisville to Colorado. His successor in the University of Louisville has not yet been appointed.

DR. JOHN G. CECIL, who resigns the chair of theory and practice of medicine in the Louisville Medical College, has been elected to succeed Dr. Bailey. Dr. Cecil was formerly assistant to the chair of obstetrics and gynecology in the University of Louisville, before his election to the chair in the Louisville Medical College, which he has held for four years.

DR. WILLIAM BAILEY, who for fifteen years has occupied the chair of the medical department of the University of Louisville, has resigned his position because of failing health. Dr. Bailey is a member and ex-president of the American Public Health Association, ex-president of the Kentucky State Medical Society and a member of the State Board of Health. He was a member of the Faculty of the Hospital College of Medicine before his association with the University of Louisville.

SUMMER VACATIONS.

Dr. J. B. Marvin and family will spend the month of August in Nova Scotia; Dr. L. S. McMurtry and Dr. J. M. Mathews will spend August at Rockaway Beach with President-elect C. A. L. Reed; Dr. Henry E. Tuley will spend his vacation the latter part of August at Woodmont, Conn.

KENTUCKY UNIVERSITY.

The Medical Department of the University will erect a commodious chemical laboratory building in the campus adjoining the college building, so as to make a large amphitheater in the upper portion, with a seating capacity of 350.

DOES NOT REFER TO THEM.

We are in receipt of the following protest from Dr. M. F. Coomes, of the faculty of the Kentucky School of Medicine:

To the Editor:—Our attention has just been called to a criticism of a medical college by the Illinois State Board of Health, published in THE JOURNAL of July 7, p. 45. As this criticism refers to no particular school, but mentions that the gentleman matriculated in January, and was to have been graduated about the 1st of July, it must be considered to apply to one of the only three schools in this country that begin sessions in January and close in July, namely: the Kentucky School of Medicine, the Hospital College of Medicine, and the Medical Department of Kentucky University, all located in Louisville. As a member of the faculty of the Kentucky School of Medicine, I appeal to your sense of justice, and request that you publish this letter, and give the name of the school referred to.

In a letter of same date Dr. P. Richard Taylor, Secretary of the Hospital College of Medicine, says:

I do not wish to put any school in an awkward position, but I do not want the Hospital College of Medicine to receive censure for the violation of the Association's rules when the blame justly rests elsewhere. I think an explanation of the article through the columns of your journal is due the Hospital College of Medicine.

As Drs. Coomes and Taylor deny that the item refers to the colleges they represent, it is not necessary to mention the name of the college referred to, especially since it has acknowledged its mistake by correcting it. Further, there are six medical colleges in the United States whose sessions begin in January—not three, as stated by Dr. Coomes.

NEW YORK.

DR. MARY L. BENOIT has been appointed physician at the State Custodian Asylum for Women at Newark.

DR. WILLIAM A. WHITE has been appointed first assistant physician at the Binghamton state hospital.

New York City.

THE Brightside Day Nursery and Kindergarten is to have a new five-story brick structure that will cost $35,000.

DR. LUCY HALL-BROWN sailed on the *Mesaba*, July 14, for Europe. She is a delegate to the Congress of Hygiene, the International Medical Congress, the Congress of Electro-Therapeutics, and the Congress of Secondary Education.

A FIVE-STORY brick hospital building for the German Hospital and Dispensary is to be erected at a cost of $120,000. Plans for changes in the building adjoining the above site at a cost of $30,000 are also before the building bureau.

THE FLOATING HOSPITAL.

The twenty-fifth anniversary of the St. John's Floating Hospital was celebrated by a trip down New York bay by members and officers of the guild. These, together with the children, left the dock on the *Emma Abbott* and returned to the city on the *Helen C. Juillard*. The *Emma Abbott* was the first boat fitted up by the Guild as a floating hospital, and, since her first trip, on July 19, 1875, she has carried 826,312 mothers, sick babies, and delicate children. The first three years of her service she made three trips a week from two landings, and from that beginning the work has increased until now two boats make six trips each a week from the two sides of the city, touching at Harlem, Williamsburg, and Brooklyn, and from 500 places of distribution tickets for the trips are given out to the mothers of children who need the fresh air and attention of the nurses and doctors, with good sweet milk, a substantial dinner at noon for the older ones, and salt-water baths for all. The trained nurse department was started in 1887, the salt-water bathroom the following year, and improvements large and small have been made each year until a system of handling and treating children almost perfect has been reached. The salt-water bathroom on board of the boat is one of the ideal features.

INDIANA.

DR. F. M. WELLS, Charlestown, has been appointed a surgeon in the United States Army, with the rank of captain, and has been ordered to Manila.

Indianapolis.

AT A concert given recently for the benefit of the Eleanor Hospital for Sick Children, about $150 was made.

THE NEW staff of St. Vincent's Infirmary has been appointed, as follows: visiting physicians, Drs. Frank Morrison, C. E. Wright, W. M. Wright, R. O. Alexander, S. E. Harp, Hannah Graham, C. Hadley, A. B. Graham, F. Wynn, T. Potter and E. A. Brown; visiting surgeons, Drs. J. H. Oliver, J. H. Ford, H. O. Pantzer, J. A. Sutcliffe, W. M. Wright and D. Ross; eye and ear, Drs. J. L. Thompson, F. A. Morrison, D. A. Thompson and J. J. Kyle; gynecologists, Drs. L. H. Dunning and O. G. Pfaff; rectal surgery, Drs. Geo. J. Cook and A. B. Graham; obstetrics, Dr. L. Burkhardt; throat and nose, Dr. L. C. Cline; house physicians, Drs. D. M. Reynolds, R. Hester and G. L. Guthrie.

LOUISIANA.

The following additions have been made to the staff of the New Orleans Polyclinic: E. M. Dupaguier, professor of clinical therapeutics; Otto Lerch, clinical diagnosis; J. J. Archinard, clinical microscopy and bacteriology; H. S. Cocram, clinical gynecology; J. A. Storck, diseases of the digestive apparatus; F. A. Larue, operative surgery and
The same institution has purchased the N
ium, which will be conducted, as heretof
the New Orleans Training School for Nu
scale.

MINNESOTA.

Dr. Percy Aling has been installed resident physician in Stillwater City Hospital, to take the place of Dr. T. R. Thomas, resigned.

Dr. F. F. Westbrook, director of the state bacteriologic laboratory, has made a report on rabies. Since October, 1896, 31 positive cases have been examined. St. Paul had 8, Minneapolis 5, Montevideo 4.

The State Board of Health has recommended that medical inspectors be employed by the boards of education in the various cities of the state. They believe that it would be of special advantage at the opening of the school year.

CONNECTICUT.

Dr. Henry Fleischner has been elected president of the New Haven Board of Health.

Dr. G. W. Russel, of Hartford, has been elected president of the medical board of the asylum for the insane at Middleton, and Dr. G. R. Shepherd, Hartford, secretary.

The report of the State Board of Health for the month of June shows that there were 1121 deaths, being 100 less than were reported for May, and 73 more than were reported for June of last year. The death-rate was 15 for the large towns and 14 for the small towns, making it 14.7 for the state.

NEW JERSEY.

Dr. Frank Scott Gordon has been appointed assistant house physician in St. Nicholas Hospital, Newark.

Dr. W. W. Fox, formerly resident physician in the Atlantic City Hospital, has accepted a post in the Orthopedic Hospital, Philadelphia.

The state dairy inspector is conducting an examination into the quality of the milk furnished by dealers in different parts of the state. In Bridgeton, two persons have already been arrested for selling milk of a poor quality, and a number of dealers in Trenton will shortly be arrested for using formaldehyde as a preservative.

CALIFORNIA.

A new hospital will be commenced at once in Redding, plans having been accepted for a $10,000 structure.

At the annual election of officers of the San Jose Board of Health, held July 14, Dr. J. Underwood Hall was chosen president, and Dr. Robert Caldwell, secretary.

The new St. Luke's Hospital in San Francisco will have four large pavilions, and work will be commenced immediately on one, for which $50,000 has already been appropriated. For the entire group about 225,000 will be required.

OHIO.

Dr. John Upham has been appointed to the department of the principles of surgery and clinical surgery in the Ohio Medical University at Columbus.

The opening of the new Lawrence Hospital in Columbus occurred July 6. It will be devoted exclusively to the treatment of women. Dr. F. F. Lawrence will be surgeon in charge and chief of staff. Dr. Starling Loving is consulting physician, and Dr. E. G. Carpenter, neurologist.

CANADA.

British Columbia.

The fight over lodge practice continues in Victoria, B. C. The doctors have now carried their grievances into the lay press. It is understood that the two physicians who were expelled from the Victoria Medical Society on account of contracting with the societies, have abandoned the work, but are still at loggerheads with their confrères.

QUARANTINE ON THE PACIFIC COAST.

Dr. Montizambert, Director of Quarantine, has left Ottawa, accompanied by Dr. Higgins, of Montreal, a skilled bacteriologist, for British Columbia, for the purpose of investigating the conditions under which the quarantine service is being maintained along the frontier and at Pacific Coast points. The Director-General will make a personal investigation with a view of determining whether the present quarantine restrictions governing travel in Canada may be relaxed, as it is now understood that the outbreak of smallpox in the American mining camps has been completely mastered by the medical authorities there. Then the drawbacks to travel by steamer between the United States and Canadian points in the West will be minimized as far as possible, provided no risk will be run of the disease entering British Columbia. Dr. Higgins has been appointed assistant to the quarantine officer at Williamshead, B. C. This appointment has been made at the present time, as one can never tell at what moment a suspected case of plague might be landed at the Williamshead quarantine, and the importance of having a practical and proficient bacteriologist on the spot, prepared for any emergency, is apparent.

Toronto.

Dr. W. Lash Miller, who since the resignation of Professor Pike has been acceptably filling the chair of chemistry in Toronto University, has been offered and will accept a position on the staff of Cornell University. He has been connected with the department of chemistry here for many years, is a Ph.D. of Munich University, and his loss will be a keen one to Toronto, for he is looked upon as one of the strong men in chemical science.

The contagiousness of consumption and the dangers to the public from the proximity of a consumption sanitarium has been aired in the Toronto courts this week. A short time ago Dr. Playter rented a dwelling-house on the northern confines of the city and started in to run a consumption sanitarium. The neighbors objected; and the medical health officer condemned the institution in unmeasured terms. Judgment has been deferred, but it is altogether likely that it will be discontinued, as public opinion in the neighborhood is too strong against it.

Montreal.

Smallpox is *spreading rapidly*. Four deaths occurred during the past week, and six new cases have appeared in different parts of the city. Nine doctors have been engaged by the Hygiene Committee to go the rounds of the houses, to see if persons have been vaccinated, and if not, to vaccinate all who do not oppose the operation. Those who refuse will be reported to the health officer, who will decide what shall be done with these cases.

The death-rate in Montreal the past week was exceedingly high. No less than 116 children died. The normal death-rate, including children and adults, is 125 per week. The total number of deaths in the city last week was 199. The principal causes of death were as follows: infantile debility, 116; diphtheria, 2; scarlet fever, 5; typhoid, 1; smallpox, 1; and consumption and other chest diseases, 30.

REPORT OF CASES OF TYPHOID FEVER IN THE ROYAL VICTORIA HOSPITAL IN 1899.

Ninety-eight cases of typhoid fever were treated in the wards of this hospital in 1899. Of these, 65 were male and 33 female. The mortality was higher for 1899 than for any other since the hospital was opened, there being seven deaths, or a mortality of 8.16 per cent. Hemorrhage was the cause of three deaths; another from hemorrhage and perforation; another from perforation alone; and two cases from profound intoxication. On an average the patients were admitted on the seventh day of the disease. With reference to the age, the average age of all the patients was 23 years, the youngest being 5½ years; the oldest 58. Under 10 years there were 4 cases; between 10 and 20, 21 cases; between 20 and 30, 40 cases; between 30 and 40, 16 cases; between 40 and 50, 4 cases; over 50, 1 case. During August the largest number of cases were admitted; the smallest during the month of December. Of these 52.3 per cent. developed during July, August and September; 18.6 per cent. during April, May and June; 18.4 per cent. during October, November and December, and 11.7 per cent. during January, February and March. The average number of days in the hospital was 39.5 days; the average duration of fever was 24.6 days; the longest period of fever was 58 days, while the shortest period was 8 days. A study of the symptoms is interesting: in 95.4 per cent. of the cases the onset was gradual. In two of the cases pain in the abdomen was severe, localized and of sudden onset, simulating appendicitis. Chills occurred at the onset or during the first week in 17.4 per cent. Enemata were given in all cases of constipation. Epistaxis occurred at the onset in 18.6 per cent. Vomiting was present at the onset in 34 per cent. of the cases. Delirium was present at the time of entry into the hospital or during the course of the disease in 18.6 per cent. of the cases, and in nearly every case it was of low muttering character. An eruption was present in 72 per cent. of the cases, the earliest appearance of the rash being on the fourth day, the latest appearance on the fortieth day of the disease. In one the rash appeared only during the relapse. The shortest duration of the rash was three days; the longest, 27 days; the average, 11 days. The spleen was palpable in 67.4 per cent. of the cases; in one on the first day of the disease; on the average, it was palpable for twelve days. A definite relapse occurred in 11 cases, 12.7 per cent. The longest duration of relapse was 29 days; the shortest, 8 days; the average, 18 days. The highest temperature recorded was 106.4. The average maximum temperature in all the cases was 103.4 F. With regard to the Widal test, this test was employed in all the cases, and in only 4 of them was it negative throughout the course of the disease; three of these were regarded as abortive typhoid. The reaction appeared in one case as early as the fourth day of the disease. In one case it was not positive until the 18th day. It was present on the average on the 8th day. The reaction has been tried in six cases at date of discharge from the hospital, and in every case has been positive. The following is a summary of the number of cases of typhoid fever admitted into this hospital for the six years ended 1899: In 1894, 84 cases, 3 deaths; 1895, 84 cases, 4 deaths; 1896, 72 cases, no deaths; 1897, 75 cases, 7 deaths; 1898, 93 cases, 4 deaths; 1899, 86 cases, 7 deaths.

New Brunswick.

MARITIME MEDICAL ASSOCIATION.

The tenth annual meeting of this Association was held in the city of St. John on the 18th and 19th of July, there being an exceptionally large attendance present. In welcoming the Association, Dr. Christie, the president, was followed by Mayor Daniel, himself an M.D., who closed his address by referring in a touching manner to the death of Lieutenant Borden in South Africa, who before offering his services in the Transvaal was a third-year medical student at McGill, and who was the only son of Canada's Minister of Militia, the Hon. Dr. Borden. Mayor Daniels moved a resolution of condolence to Dr. Borden, which was seconded by Dr. Farrell, of Halifax. Drs. Daniel, Farrell and McLellan were appointed a committee to draw up the resolution of sympathy. On the afternoon of July 18, the members of the Association were taken down to Partridge Island and given an opportunity to inspect the quarantine station there, which possesses the most modern disinfecting plant in the Maritime provinces. Later on, in the afternoon, the medical graduates of McGill College met in the Medical Society's rooms, Dr. Scammell in the chair. In the place of the provincial societies, the Maritime graduates decided to substitute the Maritime Society, with the following officers: Dr. W. H. Hattie. Halifax, president; Dr. J. H. Scammell, St. John, first vice-president; H. D. Johnson, Charlotte County, second vice-president; G. G. Corbett, Musquash, secretary-treasurer; executive committee, F. H. Wetmore, Hampton; C. M. McLean, Sussex; J. G. MacDougall, Amherst; Alex. McNeill, Kensington, P. E. I. They will meet next year in Halifax on the day previous to the meeting of the Maritime Medical Association. The papers read at the meeting of the Association were of the first order; and the discussions were keen and interesting, the meeting being a pronounced success and one of the most successful in the history of the Association.

Prince Edward Island.

PRINCE EDWARD ISLAND MEDICAL SOCIETY.

The annual meeting of the Medical Society took place on the 5th and 6th of July, and there was a large attendance. Advertising was a theme for much discussion, as there had been several who had been complained of on account of the publication of "brilliant" operations in the lay press. It was unanimously condemned by the Society. The election of officers resulted as follows: president, Dr. Sutherland, Bedeque; vice-president for Prince County, Dr. Rose; for Queen's Dr. W. Robertson; for King's, Dr. Barnes; secretary, Dr. S. R. Jenkins; treasurer, Dr. F. F. Kelley.

PARIS LETTER.

HOW THE CONGRESS WILL BE REPORTED.

It is not known as yet how the daily reports of the meetings of the Thirteenth Medical Congress will be published. The *Bulletin Médical*, which is under the direction of Professor Graucher and Professor Lannelongue, the president of the congress, was to have undertaken this work, which would cost about $500. This paper would have borne the title of "Official Journal of the Congress." Everything had been decided, but unfortunately one of the members of the syndicate of the medical press was not present at the meeting which took place, and he objected to this title being given to the paper, saying that such a course had never been followed before. As a result of these complaints, the director of the *Bulletin Médical*, Dr. Janicot, has given up all idea of doing the work, and at present it is hard to say how it will be carried out. Dr. Chauffard, the secretary of the congress, is at present occupied in finding some means of getting together a sufficient number of men to write out the reports by stenography. Such an undertaking would necessitate ample time and can not be undertaken at such short notice, so that as far as official reports are concerned, it may be questioned whether any very good result will be obtained. A description of the medical exhibit in the Ville de Paris building has already been given. Besides this there are, of course, at the Champs de Mars different sections where surgical instruments are shown. At the end of the Champs de Mars, on the right-hand side, the Presbyterian Hospital of New York has established an exhibit representing part of its hospital equipment. There is also an exhibit of the "Femmes de France." This association of the Women of France was founded some six or seven years ago, and is intended to render service in time of war. One of the small steamboats that carry passengers on the Seine was chosen as a means of showing how the transportation of wounded can be carried out, and the advantages that accrue from using this means of moving them from place to place. A species of tent has been raised over the middle part of the boat, and such cases as are not too badly wounded would be placed under this awning. The hammocks are hung by springs so that jarring is prevented, and the floor is covered with linoleum. This is not a type of a hospital-ship, but only serves to illustrate one of the most advantageous methods of carrying the wounded.

The Secretary-General, Dr. A. Chauffard, states that special and independent rooms will be set apart for the different national committees, in the buildings of the Faculty of Medicine. The members of the Congress will find installed, a post and telegraph office. The members can have their correspondence addressed as follows: Dr. X——, Membre du XIIIe Congrés International de Médecine, Paris.

THE NEW TREATMENT OF PHLEBITIS.

One of the subjects of discussion "à l'ordre du jour" in the hospitals is the new treatment of phlebitis, advocated by Dr. Dagron, a former interne of the Paris Hospitals. The leading feature is the use of massage to prevent ulterior stiffness and loss of power due to prolonged immobilization. Instead of following out the routine treatment of keeping the patient in bed for a very long period, Dr. Dagron, in his recent article in the *Presse Médicale*, advocated massage after the first general symptoms were over. During the first week, or rather as long as general symptoms of infection exist, nothing should be undertaken. The case should be watched, and perfect quiet and rest of both limbs insisted on. Two days after all general symptoms have disappeared and the edema has begun to diminish, mobilization can be undertaken very gently at first. These movements must be undertaken by the physician, and should be tried in a progressive manner from the foot upward. The toes are to be flexed and extended, and made to describe different movements, the tarsus and metatarsus are brought into play, but great care should be undertaken not to flex the thigh upon the pelvis, however. It should be borne in mind that no pain should be caused by these movements. The following days the patient herself can undertake these movements without following out any special order, but during the course of the second week, no flexion of the thigh should be allowed, and the patient must not be allowed to sit up in bed. Du [illegible] the cou [illegible] the second week an experienced anatomist [illegible] be to map out the dangerous zones and the safe ones, and exercise a little gentle massage. At this period the education of the venous circulation can begin. The patient can be placed with her legs hanging outside the bed, and in this position they will of course get congested and edematous. A little gentle massage will be found of service afterward. A few days later she can be placed on an inclined plane and lifted up to an angle of 45 degrees, then perfectly upright. During the fourth week some passive movements of flexion of the thigh are carried out; the patient is allowed to make a few steps; the latter should be of the same length. No sticks nor crutches should be allowed, so as to prevent any bad habits being acquired. A certain amount of redness and edema may appear, but will vanish after rest in bed. As for trying to sit up, it is found useful to use a number of cushions to cause variations in the angle allowed. When this has once been carried out, the patient can be told to carry out the treatment by herself. Dr. Dagron would seem to have derived good results from this form of treatment.

SYPHILIS OF THE INTESTINES.

At the last meeting held by the Academy of Medicine, Dr. Lereboullet and Dr. Fournier spoke on a very rare affection: syphilis of the intestine. Dr. Lereboullet spoke of a case where he had found symptoms of enterocolitis, abdominal pains, and discharges resembling the expectoration in pneumonia. There was also noticed pronounced swelling of the cervical, axillary and inguinal glands. The patient had a history of syphilis. Dr. Fournier advised a syphilitic treatment which was carried out by using injections of mercurial oil and iodid of potassium. After eight days the patient had improved very much, and after a certain lapse of time he was quite transformed. Dr. Fournier said he had only seen twelve cases of this disease in his practice, and added that it was often enough not recognized. Dr. Fournier also spoke of infantile diarrhea, which was sometimes due to hereditary syphilis, and would be readily cured by the use of Van Swieten's solution. Mercury was the best preparation, as it had a fundamental and eradicating action, iodid of potassium could only efface temporarily the lesions that had been formed. External treatment should be used so as to spare the intestines and stomach, and frictions or injections employed.

IS SYPHILIS A PRODUCT OF THE OLD WORLD?

It has been a question often brought up to know whether syphilis was of European or American origin. Dr. Zambaco Pacha, who has become quite an authority on such subjects as leprosy, Morvan's disease and kindred affections, presented some photographs of bones found in Upper Egypt, and dating from eighty centuries back. The bones showed indications of suppurative osteitis, and enlargement of the femora, tibiæ and peronea was plainly perceptible. The disposition of the lesions was such that Professor Lannelongue admitted that they seemed to be of syphilitic origin. This would seem to prove that syphilis has existed in the Old World from primeval times. Dr. Fournier examined the photographs and declared that there was no sure sign that the lesions were of syphilitic origin. The simple examination of a bone is not sufficient to demonstrate the existence of syphilis. The common varicose ulcer produces sometimes hyperostosed tibias which are similar to those caused by syphilis; the same can be said of typhoid fever. Dr. Zambaco insisted on the great number of lesions observed, but Dr. Fournier said that tuberculosis would sometimes produce similar results.

Correspondence.

The Plague.

New York, July 18, 1900.

To the Editor:—May I presume to commend entirely your most timely and well considered article upon the plague situation in San Francisco? The infection with plague of San Francisco's Chinese quarter; the destruction by fire of such a shameful aggregation somewhere in American territory—and the consequent scattering of infective material broadcast—and the tedious and hampered efforts to control the infection, which can not be assured and can only succeed as the result of the most patient attention and inconceivable expense, were matters of confident prediction by me as long ago as the summer of 1896. The present justification of my then statements is not a matter for rejoicing: but I do take unusual pleasure in stating that the only persons who interested themselves in studying the bacillus of plague, which I brought to the United States with me then, were Dr. Douglas W. Montgomery, of San Francisco, and then P. A. Surgeon J. J. Kinyoun, United States Marine-Hospital Service, who was at that time in charge of the bacteriologic laboratory of his service in Washington. The singleness of purpose and the devotion of these gentlemen to true professional ideals are beyond any commendation of mine; but I am endlessly pleased at your thorough recognition of their intents.

In conclusion, I trust that my interest in the matter of plague and my slight acquaintance with it may justify these protests against current errors: 1. That humbleness of station in life and disregard of occidental ideas of personal or of domiciliary cleanliness are essential factors of predisposition to plague. It might, I think, quite as reasonably be contended that a thoroughbred horse is not as liable to glanders as a cart-horse, nor so likely to die of the disease, should it nevertheless have been contracted. I should not consider it a mistake to repeat to the laity, with the iteration and insistence of a machine-gun, that plague, like glanders, and the various specific acute infections to which nearly all animals in their turns are subject, seems to have been designed *to kill*, and that there is much evidence to show that it will do its work fairly well under almost any conditions. Its unusual danger lies in the fact that it may be spread by many more diverse agents—*such as the rodents, blood-sucking insects and vermin*—than most other acute infectious diseases. 2. The weak, not to say maudlin, wails that there is no specific against its ravages. Haffkine's inoculation is a reasonable protection during active exposure; and Yersin's serum affords more chances of recovery to a victim seized by it than is usually believed, so it seems to me. I hold it greatly to the shame of the hygienists of the United States that the work of this single-minded man of science should have been almost entirely neglected in this country. 3. That street-cleaning and the like is more important than the insuring of correct death certification. By knowing absolutely what is being dealt with and by the correct management of cases as they occur, *and by these means only*, in the humble opinion of the undersigned, may plague be successfully dealt with. And the cost will be large—very!

Yours most sincerely,

W. F. Arnold, P. A. Surgeon, U. S. N.

The Paris Exposition.

To the Editor:—I send you this, thinking that a letter relative to medical and surgical matters at the Exposition might be of interest to readers of The Journal.

The exhibits in this line constitute Class 16 in Group 3 of the catalogue, and include not only everything pertaining to medicine and surgery but also all objects dental and the instruments of the veterinary surgeon. The jury for this class is composed of fifteen members, only three of whom are not Parisians and one of these three is a Frenchman, viz., the noted surgeon, Reverdin, of Geneva. Only one member is not a physician, Leclerc, our secretary, and also a leading local manufacturer of surgical dressings, sutures, etc. But one of the resident members is not a native-born Frenchman, though he has lived in Paris for the past fifteen years. I refer to Dr. de Christmas, who is a Dane, and is physician to the Danish legation here. For the rest, they are men of high standing, being, for the most part, professors to the Faculty of Medicine and members of the Legion of Honor, and all are Fellows of the Academy of Medicine. The president of the jury is Professor Pinard, the obstetrician. Then there are Galippe, chief of laboratory to the Faculty of Medicine; Pozzi, the gynecologist, at present also senator of France; Professor Berger and Dr. Tuffier, the well-known surgeons; Nocard, the head of the Agricultural and Veterinary School at Alfort; Professors Dentu, Hartmann, etc. The two other members are Eschbaum, of the orthopedic firm at Bonn, for Germany, and myself for the United States. Our work, which is now almost completed, has been most interesting, agreeable and instructive.

All the prominent countries are fairly represented, yet it is much to be regretted that the United States did not send specimens of the products of a greater number of her leading houses, who understand so thoroughly the art of making things coming under this class. There are, in all of our large cities, makers of instruments and of other medical, surgical, dental, or veterinary supplies, who would, doubtless, have done well to show their wares. Such names, for example, as Tiemann, Meyrowitz, S. S. White, and Dohme, to say nothing of many others, do not appear upon the list. In view of these facts it were almost a pity that we have not a national law similar to that of certain of the European countries, known as "Imperial Decree," which dictates concerning by whom the nation desires to be represented in any exposition, and also as to what articles shall constitute the exhibits.

One of the beneficent provisions made by the managers of the exposition is that practically all of the objects shown in any given group or class are situated close together in one building; mostly all of those in our group, for instance, can be found in the northwest wing of the structure on the Champs de Mars. A few of the smaller nations, however, such as Greece, Roumania, and some of the lesser South and Central American republics, have these exhibits installed in their government pavilions.

We began our work with the French exhibits, among which we examined examples of the best output of 125 different manufacturers, of whom, not to exceed a bare half dozen are located outside of this wonderful city itself. This means that Paris is not only the medical center of France, but of a large portion of the civilized world, besides. Many of us in the United States have no proper conception of this fact. We are, as a rule, fully cognizant of the importance of Great Britain, Germany, and Austria as regards their medical men, literature, institutions, discoveries, and manufactures, all because of the dominant races which make up the bulk of our 78,000,000 of inhabitants. We have not among us a sufficient number of those whose knowledge of France and whose sympathies with her are great enough to divert thither a just proportion of the vast armies of American students of medicine which are constantly invading Europe. But we will learn better—we are learning better.

In keeping with the enterprise which is characteristic of Frenchmen of affairs in general, has been that manifested by these exhibitors; and, in comparison with that evinced by other nations it redounds vastly to the credit of the former. By timely notices each one is warned as to what day he may expect the jury to visit his show-case. Our Gallic friend is always ready. If, for any reason, he can not be present at the appointed time, he comes before the jury in the committee-room, and asks for another occasion. Arrived at his space we find a table upon which to place the objects to be examined and chairs to seat the jury. He does not leave to a trusty *foreman* or other employee the demonstration of the articles on which hang his reputation, but he is on hand in person. He knows just what it is incumbent on him to show, he knows how to show it, and he knows—as none other does—how to talk to the point. Moreover, an average Frenchman is more than an average orator. Even the most arrant and unmitigated quack or charlatan among them—and we came across several of these—can almost make something out of worse than nothing.

In another letter I hope to tell of some of the more interesting things we have seen in our particular department. It may not be amiss to state in closing, by the way, that we have seen many models and embodiments of ideas which I have been proudly and confidently regarding as of American origin, but I have heard very few attributed to that blessed source.

CHARLES H. BEARD, M.D., Chicago.
Member International Jury of Awards, Class 16.

Colored Tents for Hospital Corps.

NEW YORK, July 20, 1900.

To the Editor:—I note in THE JOURNAL for July 21, under the above caption, a letter from T. R. Perry, M.D., of Alabama, in which he makes a very apt suggestion; but would like to bring the fact to the notice of all concerned, that the National Volunteer Emergency-Service Medical Corps is the only organization in the civilized world making use of a distinct medico-military system of immediate identification. We have tents alternately striped green, red and white, the colors of our corps; our flag is also eminently distinct and appropriate; and our uniforms are gray, trimmed with green and red, easily distinguished, and neat and clean; thus our medical officers are instantly recognized. It is hoped to make this system international, some of the foremost powers have given favorable consideration to our plans already. Our office at 304 West 104th Street, will be pleased to furnish any specific information desired.

J. ADELPHI GOTTLIEB, M.D.

Association News.

Is Your Address Correct?

A list of members of the AMERICAN MEDICAL ASSOCIATION will be published in an early number of THE JOURNAL. It is important that this list be correct, and we would, therefore, ask each member to examine the label on his wrapper and, if not correct, notify us immediately so that the name may be correctly printed in the list. Subscribers who are eligible for membership and desire to be enrolled are requested to make application at once so that their names also may appear in the published list.

American Medical Association.

The following are a few of the comments on the last meeting of the ASSOCIATION:

The American Medical Association at Atlantic City.—The month of June is almost universally acknowledged to be the most delightful of the year, hence it is a fortunate time for the meeting of the greatest medical organization of the land. When, added to this, it chooses its place on the seacoast to hold its annual convention, especially at so charming a point as Atlantic City, there is little left to be desired as to time or place for such a gathering of distinguished men and women from all parts of the country.

The meeting held June 5-8, 1900, will ever be conspicuous for size, quality of attendance and work done, and for good feeling engendered. The weather was delightful the whole time, and everybody seemed contented and happy. The sections were well managed, and the attendance at each was more than ordinarily good, while the work in some was of a conspicuous character. The weekly journals have chronicled this and we shall content ourselves with this general allusion to the general fact.

The registration was over 2000, which classes the meeting among the largest ever held. This is an indication of the growth of the republic and of the increasing interest manifested in the advancement of medicine along the lines of scientific research. In the distribution of the offices there were no manifestations of unfairness, hence there are no heartburnings left behind. The two most conspicuous candidates for the presidency were men of acknowledged ability and both were well equipped for the task. Dr. Wheaton, of St. Paul, is one of the most eminent surgeons of the Northwest, and every way worthy of the place for which his friends urged him with a spirit of manliness that deserved success. That he was not chosen is no reflection on the candidate or his followers. The spirit in which the canvass was conducted augurs well for his success next time.

Dr. Charles A. L. Reed, of Cincinnati, the president-elect, came to his office with a prestige vouchsafed to few, and perhaps surpassed by none. He is in the very prime of a well-rounded manhood, a scholar of ripe culture, natural and graceful speaker, and has an acquaintance with the profession in the Western hemisphere second to no member of the Association. That his administration will result in great advantage to the cause of medical science admits of no reasonable doubt. By a sad *contre-temps* Dr. Reed was summoned home on account of a grievous family affliction, just at the mo when name was offered to the convention as its n

The president at once courteously introduced Dr. Reed, and the latter accepted the office in a few eloquent words that well bespoke the character of the man who had but just received at the hands of his colleagues the highest indication of the esteem and regard of a great profession.

That one extreme follows another was exemplified again in the selection of the next place of meeting—St. Paul, June 4-7, 1901. The remoteness from the center of the city chosen will perhaps prevent a great attendance, but it will be a good meeting, and warm hearts will greet the visitors.

As many of the members were returning home they were arrested on their way through Philadelphia by invitations to partake of hospitalities, both public and private, that further exemplified the proverbial courtesy that reigns in the city of brotherly love. The Medical Club, on Saturday evening, June 9, tendered a reception to Drs. Abraham Jacobi, of New York; Alonzo Garcelon, of Maine; Frank Billings and George H. Simmons, of Illinois; and J. W. Bodine, of Kentucky. The Bellevue, where the reception was held, was crowded to overflowing, and, between the supper, the speeches, and the geniality of the hosts, good fellowship was at large until midnight.—*Buffalo Medical Journal*, July.

Several Reasons for Attending the Meetings of the American Medical Association.—If we were asked what one thing most impresses the man who attends an annual meeting of the American Medical Association we should say a sense of littleness. Littleness in the thought that in the crowd of representative men from all parts of the country his identity is lost. He may be the most prominent physician in his community but there he finds those who never heard of him and care less for him. Instead he sees men whose reputation is not confined to one locality, and whose opinions are welcomed by even those who have no personal acquaintance. He is as effectually lost as if a stranger in a strange city. Littleness in point of knowledge—for every day and everywhere he runs across men discussing topics of which he is ignorant, displaying a knowledge which he has never had, and while if opportunity were given he might show as great superiority on some topic, as a rule the occasion does not arise, and he feels as if he does not have a fair chance to display himself.

To a thoughtful man this can have but one effect: he returns to his daily routine of work imbued with a determination to make an advance in his own personal requirements before another year, to study and understand the subjects in which he feels he is not well versed and, if for no other reason than this incentive to renewed effort, a visit to the National Association is well worth any man's while. But there are other things which make attendance valuable.

The vacation, the relief from business care and the change of scene afford needed rest, the pleasant acquaintances and the social functions give enjoyment, while the trip itself to an unfamiliar locality broadens a man and increases his sense of satisfaction that he lives in the United States.

The bad politics which for years has marred these meetings is now absent and the mutual admiration society from a certain section of the country is no longer in evidence. The general sessions are dignified, and personal ambition and petty spite have no longer the floor, and a good thing it is, too.

In many matters there is room for improvement; there are too many papers, the time for discussion is too limited, too many men desire recognition, too few do original work of merit, too many talk as if addressing a body of students, too many like to refer to "my assistant," too many talk and say nothing, the social functions are either too numerous or conflict with the scientific, there are too many side shows, but when all these objections are weighed and placed against the good features there is but one verdict.—*The Providence Medical Journal*, July.

American Medical Association.—The last meeting of this growing Association has just been held under more favorable weather conditions than are ordinarily to be expected at this time of year. The gathering was an enthusiastic one, as attested by the fact that upward of 2000 members were present. Corresponding with this attendance was a program which has rarely been equaled in the number and variety of communications presented. Of quantity, therefore, there was certainly no lack, but we are inclined to feel that in these days of excessive literary zeal in medical writing a certain censorship, tending to an improvement of the quality and the arrangement of the subject-matter, would not be amiss. Sporadic papers on such occasions are of comparatively small value, and serve rather as a personal advertisement than as a substantial addition to medical progress. It is to be hoped that this representative Association will make a virtue of necessity and bring its programs in the future within reasonable limits. Science would not suffer, and the responsibilities placed upon the broad shoulders of the medical editor would be visibly lightened. We are, therefore, quite in accord with our contemporary, the *Philadelphia Medical Journal*, when it comments editorially on the recent meeting: "There was the same plethora of papers offered, again proving how necessary it is that the officers of sections should weed and choose and limit according to their judgment and conscience, and regardless of personal influences."—*Boston Medical and Surgical Journal*, June 14, 1900.

Deaths and Obituaries.

Thomas Story Kirkbride, Jr., M.D., Philadelphia, died July 20, aged 31 years, of typhoid fever. He was a son of Dr. Thomas S. Kirkbride, the eminent alienist and superintendent of the Pennsylvania Hospital for the Insane. He received the degree of A.B. from Haverford in the year 1890, and was graduated from the medical department of the University of Pennsylvania in 1893. He subsequently spent several months in post-graduate work at the Johns Hopkins, and then entered upon his duties at the Pennsylvania Hospital as resident physician. After leaving the Hospital he went abroad for nearly three years, pursuing the study of pathology in Göttingen, Vienna, and other places. About two years ago he was elected director of the laboratories of the Philadelphia Polyclinic. He was assistant physician to the University Hospital, and assistant pathologist to the Philadelphia Hospital, and member of the College of Physicians of Philadelphia, the Philadelphia County Medical Society, and the Pathologic and Neurological societies.

Divie Bethune McCartee, M.D., for more than fifty years engaged in missionary and educational work in China and Japan, died in San Francisco, Cal., July 17. He was born in Philadelphia, in 1820, and, having secured his medical degree from the University of Pennsylvania, went to China, and in 1844 opened a mission at Ningpo. He received honorary recognition from both of these Oriental countries. In failing health for some time, he was compelled to stop off at San Francisco on his journey to New York from Japan.

S. R. Welles, M.D., Waterloo, N. Y., died July 14, aged 75 years. He was graduated from the medical department of the Buffalo University in 1848, the following year he attended Jefferson Medical College, Philadelphia, and in 1850 located in Waterloo. During the Civil War he was surgeon of the Sixty-first Regiment of New York Volunteers. He was one of the charter trustees of Willard State Hospital, and secretary of the board for fifteen years. He had served two terms in the State legislature.

Joseph E. Burke, M.D., Galveston, Texas, died July 9, aged 42 years. He was a graduate of the medical department of Tulane University, New Orleans, receiving his degree in 1882. He had won a national reputation as a yellow fever and smallpox expert, having volunteered his services during the epidemic in Brownsville and Galveston.

David P. Wolhaupter, M.D., Washington, D. C., died July 12, aged 60 years. He received his degree in medicine from the medical department of Bowdoin College (Maine) in 1862. He enlisted in the Civil War and was assigned to the hospitals near Washington. Since the close of the war, he had remained there in the practice of his profession.

John Leonard Mulfinger, M.D., died on July 21, at his residence, 926 Jackson Boulevard, Chicago, after a long illness. He was born in Chicago in 1854, and spent his entire life in that city. He was graduated from Rush Medical College in 1880, and had an extensive practice on the West Side.

J. L. Combs, M.D., Grass Valley, Cal., died July 4, of pneumonia, aged 61 years. He was a graduate of the Washington University School of Medicine in Baltimore, Md. He located in Oregon, and lived there until 1866, when he moved to California.

Roland Hammond, M.D., a graduate of the Harvard University Medical School, 1872, died at his home in Campello, Mass., July 8, aged 58 years. He was a member of the Massachusetts State Medical Society, and vice-president of the Plymouth District Medical Society.

David G. Bowman, M.D., died in Denton, Md., July 10, aged 63 years. He was a native of Philadelphia, and a graduate of the medical department of the state university there. During the Civil War he was connected with the Fifth Pennsylvania Cavalry.

F. A. Blackmer, M.D., Albert Lea, Minn., died July 11, in Minneapolis, after undergoing an operation. He was born in Ohio, in 1847, and received his education at Oberlin College and the University of Worcester, Cleveland.

A. L. Patten, M.D., Mineola, Texas, died July 11. He was graduated from the medical department of the University of Georgia, in 1851, and afterward had practiced in Texas. During the Civil War, he was surgeon of the Twenty-second Texas Infantry.

Robert J. Hill, M.D., who for thirty years had practiced medicine in St. Louis, Mo., died there July 15, aged 64 years. He was assistant-surgeon of the Forty-fifth Ohio Regiment during the Civil War.

Marion E. Gillen, M.D., Mount Morris, N. Y., died in Belleville, Canada, July 12, aged 45 years. She was a graduate of the Faculty of Medicine of Queen's University, Kingston, Ontario.

John J. McAchran, M.D,. Salt Lake City, Utah, died July 12, aged 44 years. He was a graduate of the medical department of the University of Louisville (Ky.), in the class of 1881.

Benj. W. Bartlett, M.D., Rowley, Mass., died July 6, aged 50 years. He was graduated from the Bowdoin (Maine) Medical School in 1873.

James S. Gillespie, M.D., Philadelphia, died July 20, aged 37 years, of appendicitis. He was graduated from the Jefferson Medical College, and afterward served as a resident physician to the hospital connected with it.

J. B. Newbaker, M.D., a graduate of Jefferson Medical College, 1852, died at his home in Trevorton, Pa., July 11.

DEATHS ABROAD.

We note the deaths of:

Dr. Edwin von Millengen, the ophthalmologist, at Constantinople.

Dr. Karl Lange, professor of pathological anatomy at the University of Copenhagen, and editor of the *Hospitals Tidende*, a weekly medical journal.

Arnold Schetelig, M.D., who died recently in Nervi, Italy, was born in Germany, in 1835. He studied medicine at Göttingen and Kiel, taking his degree from the latter in 1856. He practiced seven years in Hongkong, and then located at Hamburg, Germany. At the outbreak of the Franco-German War, the Senate of that city put him at the head of the Red Cross ambulance work. For his excellent service in this capacity he was rewarded with the Iron Cross. He never recovered from the fatigue experienced during the seige of Metz, and after traveling in Spain and Italy, he settled at Nervi, where he did much for the city in its development as a health resort. He was an anthropologist and archeologist of some note.

Miscellany.

Improved Technique for Rubber Gloves.—If thin rubber gloves are sterilized by dry heat—which can be done several times without injury—and dusted inside with the talcum powder used in new kid gloves and shoes, they slip on with ease and keep their shape, according to a communication from Wormser in the *Semaine Méd.* of June 20.

An Honor Long Deferred.—A monument has been erected to the memory of Dr. Jean Hameau (1779-1851), an obscure physician of the Gironde, who in 1836, at much personal loss, published a study on viruses, in which he partly anticipated the discoveries of Pasteur. The statue was unveiled recently at La Teste de Buch, where Hameau practiced. Addresses were delivered by Dr. Laude, mayor of Bordeaux, Professor Lannelongue, of Bordeaux, and others.

Medical Attendance on Police in France.—Dr. Laloy mentions in *Janus* as a "pearl in the history of the exploitation of the profession," the recent decree of the French war department that physicians, apothecaries and veterinarians who give their services gratuitously to the "gendarmerie brigades" will receive an official letter of thanks from the government after ten years, a bronze medal after fifteen years, one of silver in twenty years, and of enamel in twenty-five years, with the "academic palms."

Fixation Abscesses.—E. Bauer has been experimenting with abscesses induced with chemicals, usually turpentine, on man and animals, and states that they were always sterile and consequently have no effect on the elimination of microbes as intended when first suggested. But, he adds, in his communication to *Virchow's Archiv*, clvi, 3, that they induced protracted leucocytosis, and that this alone may be sufficient to favorably influence certain morbid processes, such as pneumonia, threatening chronic suppuration or pyemic or bacteriemic lesions.

Railroad Hygiene.—The exhibit of the Trans-Siberian railroad at Paris is attracting much attention, as comfort and hygiene have both been studied in the trains. The walls are smooth wood or tiles; the seats are covered with real or artificial leather; there are shower baths; appliances for cooling the air; gymnastic apparatus; cigar lighters; boiled water in the coolers, and a sanitary official on each train who is a trained nurse and barber. The draperies are reduced to the minimum and an automatic perfume spray is set in action as the door of the water closet is closed.

Smallpox in Nome City.—A dispatch from Seattle, Wash., bearing date July 19, states that the *Athenian* and *Sequola* are at anchor. The latter vessel left Nome City on July 3. The pesthouse at Nome is reported overflowing with smallpox cases. Government officials were erecting two other large structures. The disease has spread rapidly, and many cases are quarantined in the tents in which they were discovered. Every government and city official, and every doctor was working night and day endeavoring to check the disease. Dr. J. J. Tyler, of Chicago, who returned on the *Sequola*, said there were at least 200 cases, and that nearly twenty new cases were being reported daily.

A Checkered Career.—Dr. Heneage Gibbes, according to the *Saturday Evening Post*, Philadelphia, June 30, enjoys the distinction of being the only Chinese mandarin to hold an American office. He is English by birth, ran away from home at fourteen and went to sea. He was shipwrecked on the coast of China, and fell in with pirates, who turned him loose without clothes. After reaching a Chinese town he fell in with an Englishman who equipped him for a mission to a rebel army, from which he drifted into the Chinese service. In command of a gunboat, with a mixed crew, he patroled the coast, capturing outlaws, pirates and smugglers. On one occasion he seized a cargo of contraband opium and made for the sea. For this he was summoned into the presence of royalty and made a mandarin. His career since then has been a return to England for the study of medicine, a commission to India for a cholera investigation and a resignation to take the chair of pathology in the Michigan University. Dr. Gibbes is also to be remembered as the Health Officer of Detroit.

Enforced Abstention in Diabetes Insipidus.—About a year and a half ago Dr. A. Strubell published an account in the *Archiv f. Klin. Méd.*, lxii, of an attempt to deprive a patient with the insatiable thirst of diabetes insipidus of some of the water he craved. On three occasions he was left from five and one-half to ten hours during the night without the possibility of getting water, after having ingested two to five liters. The report says that the patient drank his urine to quench his thirst during these intervals and an impression of sensational clinical tortures was [illegible] ced [illegible] ic, which the lay press has taken [illegible] Stintzing, the chief of the [illegible] cident occurred, has recently published an "explanation" in an local paper. In this he says that, while taking the responsibility of the treatment as a whole, he yet expresses his regret that certain details were carried out in a manner of which he only learned afterward. The *Deutsche Med. Woch.* observes that the deplorable incidents could easily have been prevented by a little more care and attention. Strubell established in these tests that a sweat-bath diminishes the thirst, and he also obtained data for further research by his examination of the blood during the forced abstention.

Societies.

DeWitt County Medical Society.—This Society met in Clinton, Ill., July 12. The following officers were elected: president, A. E. Campbell, Clinton; vice-president, C. C. McMackin, Weldon; secretary, J. C. Meyer, Clinton.

Stephenson County Medical Society.—This Society met in Freeport, Ill., July 12, and officers were elected for the ensuing year as follows: president, C. R. Sheetz, Freeport; vice-president, S. C. Thompson, Cedarville; secretary and treasurer, J. F. Fair, Freeport.

Iowa Union Medical Society.—The semiannual meeting of this Society was held in Cedar Rapids, July 10. The election of officers resulted as follows: president, T. J. Shuell, Parnell; first vice-president, H. S. Raymer, Cedar Rapids; second vice-president, J. W. Kirkland, Wyoming; secretary, J. DeWitt Graham, Springville; treasurer, Geo. P. Carpenter, Cedar Rapids.

Wabasha County Medical Society.—At the thirty-second annual meeting of this Society, held in Lake City, Minn., July 12, the following officers were elected for the ensuing year: president, J. A. Slocumb, Plainview; vice-president, P. N. Kelly, Wabasha; secretary and treasurer, W. F. Wilson, Lake City. The meeting will be held in Wabasha, the second Thursday in July, 1901.

American Public Health Association.—The next meeting of this Association, at Indianapolis, will be held October 23-26. The meeting of the Section of Bacteriology and Chemistry will be held, Monday, October 22, in the Pathological Laboratory of the Central Insane Hospital at Indianapolis, and that of the regular Association will open Tuesday, October 23, in the amphitheater of the German House.

Upper Peninsula Medical Society.—The fifth annual meeting of this Society was held at Mackinac Island, Mich., July 10. The election of officers resulted as follows: president, A. Felch, Ishpeming; vice-presidents, W. R. Hicks, of Menominee, F. E. Fletcher, of Lake Linden and J. H. Bogan, of Mackinac Island; secretary and treasurer, C. E. Cruse. A memorial tablet in honor of Dr. William Beaumont was unveiled. The next meeting will be held in Menominee.

Iowa and Illinois District Medical Association.—This association met in Moline, Ill., July 13. The following officers were elected: president, Henry Matthey, Davenport, Iowa; vice-president, C. M. Sala, Rock Island, Ill.; secretary, G. E. Decker, Davenport; treasurer, Emily Wright, Rock Island.

Michigan State Medical Society.—The thirty-fifth annual meeting of this Society was held at Mackinac Island, July 11 and 12. The following officers were elected: president, P. D. Patterson, Charlotte; first vice-president, D. B. Harison, Sault Ste. Marie; secretary, D. B. Biddle, Detroit; treasurer, Charles E. Hooker, Grand Rapids. The meeting next year will be held at Battle Creek. A more detailed report will be published later.

Chicago Society of Internal Medicine.

June 18, 1900.

PROPHYLAXIS AND MANAGEMENT OF INTERSTITIAL NEPHRITIS.

Dr. Charles W. Purdy, Chicago, read a paper on the above subject. See page 216, in this issue.

Dr. I. N. Danforth—I do not think very much can be added to the admirable paper persented by Dr. Purdy, because it seems to cover the ground very thoroughly. We all know that interstitial nephritis is an affection very difficult to manage. I desire to say a few words concerning diagnosis, and then pass on to the consideration of my own treatment for this disease. My observations have been that not more than about one-third of the cases that come to me with a diagnosis of interstitial nephritis are really that disease. I should say that about one-third are simply cases of catarrhal nephritis. I had such a case to-day from Indiana. The patient was a boy, 18 years of age, whose disease had been diagnosed some months ago as interstitial nephritis, or contracting kidney. He had none of the symptoms or characteristics of this disease. He had never been exposed to any of the causes of interstitial nephritis, as far as could be learned. There was no heredity that led to it. It is true, there was a trace of albumin in the urine; the urea was up to 1.75 per cent. The urine was cloudy, and contained a little mucus. The heart was normal. There was now and then a hyaline cast, and there were quite a number of what we have stupidly called "cylindroids," that is, mucous casts. I see many such cases of so-called contracted kidney, not quite as marked as this, however, and I have for a long time wrote and taught that we ought to recognize as a distinct lesion, catarrhal nephritis. If we can make an accurate diagnosis in the catarrhal form of the disease, it is curable. There is about another third of the cases which are not interstitial at all, but which occur in advanced cardiac disease, where the cardiac affection is the initial trouble. Under these circumstances the kidneys become enlarged, congested, somewhat indurated, but not contracted. It is a type of kidney disease that Formad described first as the "pig-back kidney." The kidneys become enlarged and rounded; the capsules are distended and stretched. If you cut them a little the kidney begins to bulge out. The kidney tissue will be grayish in appearance, perhaps mottled, but not indurated. These are often mistaken for cases of interstitial nephritis, but they are what we now know as "cyanotic induration."

I desire to pass on now to a consideration of the alterative treatment, which I have long used, and, I believe, with some success, for true interstitial nephritis. I believe in the use of alterative remedies in small amounts for periods extending over weeks, months, or even years. For example, I have a case to-day, a man, 50 years of age, in whom a diagnosis of interstitial nephritis was, I think, correctly made. This patient has been under my care for seven or eight years; he is no worse to-day than he was when I first saw him, and I think he is somewhat better. He has a slight trace of albumin in the urine; there are always present a few hyaline casts, and there is more or less cardiac tension. There is a thickened left ventricle, but it has not enlarged for the past five years, so far as I can determine. He has taken almost continuously for the last three years either bichlorid of mercury, or the iodid of mercury in some form. He is taking now the fortieth of a grain of bichlorid of mercury, three times a day. Probably nine out of ten will laugh at that treatment, and those who speak after me will be very likely to ridicule it. Yet I have seen many patients improve on this treatment, and have seen the disease apparently arrested in its progress under it. In connection with this treatment attention must be directed to the diet, to sanitary measures, etc. Stimulants must be cut off, and meat and tobacco to a great extent. I agree with what Dr. Purdy has said regarding milk, and I do not think we can starve a man to death any quicker than we can by giving him a milk diet exclusively. I use the iodids, the biniodid, or the green iodid of mercury in these cases. Sometimes one seems to agree with the patient much better than another. Of the green iodid I would not give more than gr. 1/10 to gr. 1/20, but I would keep up the treatment uninterruptedly for weeks and months. Of the red iodid I would not give more than gr. 1/60, three times a day; but I insist that its effects are only realized by giving it for weeks or months together, the patient being kept under observation. During this treatment the pation must be taught as to diet, and symptoms must be met as they arise. This long-continued alterative treatment is absolute and certain in its effects. The iodid of potassium is almost as efficient, although given in small doses, not more than a grain four times a day, which is hardly enough to be worth giving, and yet it is this continuous effect which produces the favorable results. Of late years we have been dropping the old idea of the use of alterative remedies in an alterative manner, as we were taught many years ago, giving small doses of remedies which are in themselves potent, but which are continued over long periods of time, so that the patient is continuously under their influence, but their efficiency when given properly and continuously can not be doubted by any one who has thoroughly tried them.

DR. ARTHUR R. ELLIOTT—The statistics published by Dr. West, in the Lettsomian lectures of 1898, came to me in the nature of a surprise. I have not looked up the statistics to refresh my memory, but if I remember rightly, the observations he conducted, which were very striking in manner, consisted of post-mortem examinations of all cases dying in St. Bartholomew's Hospital from whatever cause, and showed that thirty-eight and a fraction per cent. of all such cases presented pathologic evidences of contracted kidney. Mahomet's earlier observations corroborated these findings in a striking manner. According to these and other observations, chronic interstitial nephritis was shown to be the most frequent of all degenerative lesions. Dr. Danforth has told us that not more than one-third of his cases diagnosed as chronic interstitial nephritis were characteristically this disease. That may be true, but I venture to say that one-third of the cases of interstitial nephritis, perhaps the majority of them, run their course to a fatal termination and die without the kidney lesion having been diagnosed or suspected during life. The disease masquerades in death reports as "heart failure," "apoplexy," "dropsy," etc., the latter a designation which has, however, fallen into desuetude. The true secret of successful prophylaxis of this disease is an early diagnosis, for when the patient is seen in the early stages of the disease, his case is extremely amenable to treatment. After the disease has progressed or advanced to that period when there are marked cardio-vascular changes, cardiac dilation, failing heart, etc., comparatively little can be done, so that the earlier a patient with this disease comes under our observation, the more amenable is he to treatment, and the more satisfactory are the results. Early diagnosis of the disease will depend upon a more widespread, careful examination of the urine, and the realization and significance of the cardio-vascular changes, since they are the most marked of the symptoms in this form of renal lesions. A more careful examination of the urine, and a clearer understanding of the significance of the cardio-vascular changes, attracting attention to the heart and arteries, would result in the discovery of a greater number of these cases. The sphygmograph is not by any means as often resorted to as it should be. The pulse of these patients in the earlier stages of the lesion is of great value in diagnosis and extremely significant. The appreciation of tension by the finger in the early stages is not by any means as striking as by the use of the sphygmograph. The treatment of interstitial nephritis is one which is almost entirely hygienic in the early stages. The less drugs the better. The regulation of the diet, as Dr. Purdy has pointed out, is in the direction of excluding nitrogenous foods. The majority of these cases have decided polyuria, although some are marked by the absence of it. The effects of the free use of drinking water are lauded in articles which have been published from time to time in medical journals, and it is customary with some practitioners to invariably direct these patients to partake freely of pure drinking water. This recommendation is one which may be too rashly interpreted by the patient, and it has been my experience to have these patients partake so freely of water as to increase the flow of urine immensely. The effect on the kidney of this excessive secretion of urine is deleterious. I have seen a number of cases in which hematuria has resulted probably from renal congestion, and also increase in the albuminuria, these urinary evidences of irritation passing away with restriction in the amount of fluid. Dr. Purdy touched upon the character of heredity in many of these cases. The hereditary character of interstitial nephritis is pretty generally recognized, but I have not seen pointed out very many times the peculiar course which the hereditary cases pursue. It has been my experience to have treated not a few cases where distinct hereditary influence was present. Perhaps it is not possible to trace in the family history a direct story of a preceding nephritis or kidney disease in the immediate ancestors, but we have as significant the history of relatives in the immediate line dying of apoplexy and of heart failure, which, in all probability, are just as likely as not to have been cases of interstitial nephritis with dilated, failing heart. With such heredity, one is justified at least in inferring the cases to have been instances of interstitial nephritis. These cases are not characterized by any peculiar symptomatic feature; they present the same picture as do others. The manner in which they differ from cases of the non-hereditary type is the way they react to treatment. The results are much less satisfactory in these than in the cases of the non-hereditary type. The disease pursues a more uniform and progressive course toward a fatal termination.

DR. ROBERT H. BABCOCK—In your note to me, Mr. President, you kindly asked me to consider the subject of nephritis in its relation to cardiac disease. I assume by that you mean not the cases of interstitial nephritis or renal changes which are encountered in connection with cardiac symptoms, and which really antedate the cardiac manifestations, but those conditions of the kidney which are associated with heart disease as the effect of the cardiac lesion. These are a congestion of the kidney which constitutes the large, red kidney, and later, after years of congestion, more or less development of interstitial connective tissue, or induration, a condition known as cyanotic induration of the kidney. I do not expect to say anything new or novel on this subject. The cases which I see, as a rule, simply present changes of the urine indicative of passive renal congestion. The cases I have under observation rarely live so long a time that the changes in the kidney have gone on to contraction of the organ, therefore, as this evening's discussion is confined to interstitial nephritis, my remarks will not be apropos. I have had a great many urine analyses made, and I am astonished to find in my chronic cardiac cases, commonly valvular diseases of course, how seldom a report comes to me, from the Columbus Laboratory, of albumin in the urine. Of course, albumin in this class of cases is due to nutritive disturbances in the glomerular epithelium, and it seems rather strange that I do not more frequently find albumin in the urine of these patients. I do occasionally encounter a case in which there is albuminuria, as typified by the following case: I have under observation a young woman with mitral regurgitation with adherent pericardium, and compensation has been partially destroyed. It has only been with the utmost care that during the past three years the condition has been held pretty much in *statu quo*. Examination of the urine has not revealed anything special other than the change of congestion. But last April, after having been very well during the winter, she began to lose flesh and to complain of pain of a neuralgic character in various parts of the body, and although there was nothing in the heart findings to explain the loss of strength, she steadily went down. Soon after this an examination of the urine showed a total volume of 660 c.c., specific gravity of 1028, urea of 3 per cent., albumin, 2.75 per cent., granular and hyaline casts. At this time she was weak and felt very miserable. The heart's action was rapid, and the usual treatment did not in any wise control its action. I immediately forbade animal food, ordered a restricted diet, including some milk, and made her drink large amounts of water. The urine changed, and examination a week later showed that she was now passing 1500 c.c. of urine in twenty-four hours, with a specific gravity of 1013; 1.3 per cent. urea, with no albumin, no casts. This was evidently not a case of interstitial nephritis, and albumin did not appear on account of congestion. There was acute nephritis, but to what it was due I do not know. Had it been a renal congestion merely, it seems to me the increased intake of water would not have remedied it. Her other treatment remained the same. Analysis of the urine since has shown practically the same findings as were noted in the second analysis. I would call your attention to the readiness with which cardiac patients who have a passive hyperemia of the kidney may contract an acute inflammation of these organs. I do not refer here to embolic infarcts. Of course we must recognize their occurrence in the kidneys as part of the changes which occur in the course of heart disease. But a chronic cardiac patient, just as a chronic nephritic patient, is for some reason specially liable to infection. He becomes infected from one cause or another without our being able to say why, and under this condition of infection the kidneys become readily inflamed in consequence of the elimination of the toxins, or of the micro-organisms of the infection. I think that in the management of chronic cardiac cases physicians should examine the urine more frequently than they do with a view to detecting evidences of acute nephritis, when, in fact, there have been no marked constitutional symptoms to lead the physician to suspect infection. Regarding the management of congested kidneys of heart disease, physicians are apt to err in the way of urging patients to drink too freely of water. If patients drink too much water in the hope that it will act as a diuretic, they only increase the congestion of the kidneys, and will really aggravate rather than ameliorate their condition. The urine is scanty, and there is frequently, notwithstanding its high specific gravity, an actual diminution in the total amount of solids eliminated. As pointed out by Oertel, in the management of cases of cardiac disease we may get better results in the way of elimination from the kidneys by a restricted ingestion of water, or in allowing just the amount of fluid which will produce the greatest amount of urine. When contraction of the kidneys occurs as a result of chronic heart disease the prognosis is most unfavorable, both because the cardiac lesion is unfavorably affected by the increased blood-pressure secondary to the renal change, and because there is not cardiac power sufficient to maintain adequate pressure in the renal arteries.

Dr. James B. Herrick—I want to take exception to some of the statements made by Drs. Danforth and Elliott, as too broad. The statement made by Dr. Danforth is to the effect that two-thirds of the patients that come to him with a diagnosis of chronic interstitial nephritis have something else. Possibly that is true with regard to the patients that come to him, but I believe the diagnosis of chronic interstitial nephritis as made by the majority of physicians is correct. Dr. Elliott made a statement, using the same figures, that two-thirds of the cases of chronic interstitial nephritis are entirely overlooked or pass for something else. I do not believe that this is true as regards the majority of physicians. Both these statements I would criticise as too sweeping. I would also take exception to one thing Dr. Purdy has said. I fully indorse what he has said regarding the importance of treating the heart in cases of chronic interstitial nephritis; there can be no question of its immense value. But if I understood him rightly, he made the statement that a very large number, even the majority, of the cases of chronic interstitial nephritis die, in reality, of heart disease. There can be no doubt that a great many patients do die with all the evidences of cardiac failure —dilatation of the heart, murmurs, insufficiency, cardiac dropsy, etc. But when we think of the great number of patients with chronic interstitial nephritis who die of uremia; when we think of the great number of patients with chronic interstitial nephritis who die from some intercurrent or complicating disease, we must admit that a great many, I should say the majority, do not die of cardiac insufficiency; and particularly would this be true if we are allowed to include those cases that die of cerebral hemorrhage, though the relation of the heart to cerebral hemorrhage may be very intimate.

I would fully indorse everything that has been said relative to the importance of heredity, enabling us to institute early prophylactic treatment. There are family cases on record where not only from one generation to another, but in one and the same generation, many members of the same family have chronic interstitial nephritis, and sometimes at a very early age, even in childhood.

Dr. Danforth said he believed he would be criticised for what he said regarding alteratives, and particularly regarding the value of these remedies. I do not recall who it was who told me of the great value of the alteratives in chronic nephritis. But I have given, I believe, with benefit, the alteratives in these cases, and oftenest in the form of Donovan's solution of arsenic or minute doses of calomel. One other point I would like to refer to; this pertains to prognosis. I have never seen a case of chronic interstitial nephritis, in which there was albuminuric retinitis, that has lived for more than a few months. I do not remember to have seen a case live longer than twenty to twenty-four months. Possibly there is nothing in this point, yet, after hearing that statement made I have watched my cases since, and whenever in chronic interstitial nephritis albuminuric retinitis was present, death has occurred inside of two years.

It may not be out of place to say a word regarding the treatment of uremia, which occurs so frequently in the course of chronic interstitial nephritis. I wish to speak of the great value of normal salt solution where the secretion of the kidneys is locked up. In many cases of chronic interstitial nephritis we find relative anuria; the albumin is increased in amount, as well as casts, and the patient has uremia in one or the other of its manifestations. The results following the subcutaneous injection of large quantities, say a pint to a quart and a half, of normal salt solution, once, twice, or thrice in twenty-four hours have at times seemed remarkable. The kidneys and skin act much more freely after this, and best of all, the patients in many instances make a beautiful recovery. I would also call attention to the value of the normal salt solution just preceding the sweats so commonly given in cases of uremia. When we sweat a patient we abstract a certain amount of water from the blood, and but a relatively small amount of toxic material, the blood being surcharged with this toxic material is rendered more concentrated by the abstraction of water. By first injecting normal salt solution under the skin, and then sweating the patient, we not only obtain much better diaphoresis, but we lessen the danger that comes from the concentration of the blood. Cases have been reported in which, following a sweat, uremic manifestations were worse, and in which it seems the blood, from too great concentration, became much more toxic. It is certainly prudent to consider this point, and even though we do not go to the extent of giving normal salt solution under the skin, we can give large amounts of water by the stomach.

Dr. N. S. Davis, Jr.—One point, it seems to me, has not been sufficiently emphasized, and it is of considerable importance from the standpoint of prophylaxis. Unquestionably, the main thing in the prophylactic treatment of these cases is to teach patients to be abstemious as regards eating and drinking. This is a difficult thing to do, because these patients naturally are hearty eaters, and have been such for long periods of time, and usually they have been addicted to taking small quantities of water and considerable quantities of those fluids which are more or less irritating to the stomach, to the liver, and sometimes to the kidneys. When such habits have existed for a long time, it is difficult to change them, and more especially in those patients for whom prophylactic treatment is of most value, patients in whom the disease is starting. They do not appreciate their own condition, consequently it is difficult to drive home the necessity of their being abstemious as regards eating, and the need of drinking copiously of good, pure water. However, that is not the point to which I wish particularly to refer. I wish to emphasize the necessity of keeping the intestinal tract as reasonably clean as possible. In these cases we have almost invariably preceding the renal trouble, or at least coincident with it, enlargement of the stomach, more or less gastritis, more or less fermentation of an abnormal character in the intestinal tract, and it is chiefly because of the products of fermentation in the gastro-intestinal tract that renal lesions develop. Renal irritants are produced there, the lesion is not due to a surplus of nitrogenous foods only or chiefly. The kidneys, like most other organs, are capable of doing a much larger amount of work than required under strictly physiologic conditions. They can eliminate much more nitrogenous matter, without harm to themselves, than is required for the maintenance of strength and health. They are able to do the work thrown upon them, providing the nitrogenous matter comes to them in a normal condition. To prevent the constant recurrence of that irritation of the kidneys which produces necrosis and interstitial changes, it is necessary to prevent the formation of those materials in the stomach and intestines, which result from abnormal fermentation in nitrogenous food. Not only must the diet be made abstemious in order to lessen the nitrogenous elimination, but in order to lessen gastrointestinal fermentation, which is especially apt to be excessive when the organs are overworked. For this reason also laxatives must be given freely and constantly to obtain copious movement of the bowel.

A word or two in regard to the administration of milk. Most individuals can not take milk continuously for a long period. It is not to be expected, therefore, in cases of interstitial nephritis, that a strictly milk diet can be adhered to even if it was needed. But experience has shown that it is not especially indicated in these cases. It can, however, be used as an element of diet in some cases. I believe it is one of the simplest forms of nitrogenous food which we can use, and one which is least likely to undergo deleterious fermentation in the stomach and intestines, and it meets many of the dietetic indications of this disease. But milk must form only one element of diet. It has often been said that a strictly milk diet is a starvation diet. That is true for most individuals. I have seen persons, and I presume most of you have, who have adhered to a strict milk diet for a long period of time, and who upon it gained flesh and strength. They used large quantities of it. They were the unusual patients, who took milk with pleasure. But these individuals are rarely met. Therefore the general statement is perfectly correct that a milk diet is a starvation diet for the majority of patients, but it can advantageously constitute one element of diet for many of these patients.

DR. ALBERT H. BURR—I was asked to speak upon the treatment of interstitial nephritis from a hydriatic standpoint. I seem to have acquired, unjustly, I think, some reputation as a medical baptist with an idea that salvation from disease can only come through tubbing. Water is an extremely flexible remedy and will often better than any other remedial measure fulfill the indications for stimulation, for elimination, and for counteracting toxic effects in renal diseases. There are a variety of ways of using water therapeutically in the treatment of conditions arising from interstitial nephritis. First, from a prophylactic standpoint, if the patient has been recognized as liable to fall into a condition of ill-health through a diathesis or tendency to nephritis, much can be done for him by hydriatic methods in warding off the condition, not ignoring, of course, other necessary dietetic and hygienic measures.

There is one element that has not been dwelt upon to-night, either in the excellent paper of Dr. Purdy, or in the discussions; I refer to the toxic element. In interstitial nephritis there has been an irritation due, I believe, to something more than the elimination of large quantities of normal wastes. The wastes from nitrogenous products are normally passed through the kidneys. That is their function. The kidneys may carry on the work of elimination to two or three times the normal amount of nitrogenous wastes without harm, as the stomach is able to bear the digestive work of overfeeding for years without serious impairment. It is astonishing to note how much abuse the stomach will tolerate and still maintain a good functional activity throughout life. To the same extent the kidneys are able to perform their function, although overworked. But there is another element—that of toxicity, auto-infections, and irritants from germ-life, and faulty metabolism—that is not due to the overwork of eliminating nitrogenous wastes. Here Dr. Danforth's idea of elimination by means of alteratives is appropriate. If the physician appreciates the tendency in the direction of interstitial nephritis he may contribute very materially toward his success in keeping the patient in a fair degree of health by suitable hydriatic measures. In these cases nothing is better as a tonic, as an alterative, or as a stimulant to the cardiac and renal functions than the morning cold plunge bath, with friction. Such a bath patients are able to take themselves. They stimulate the normal physiologic processs, and assist in carrying out efficient elimination. Let us now take a well-marked condition of interstitial nephritis, in which there will develop cardiac lesions sooner or later. There may be at times over-excitement of the heart action and over-pressure of circulation, and in this condition we often have polyuria, then the sedative effects of water are indicated, such as the application of hot or cold packs. The patient will get these sedative effects with either hot or cold, provided the application is continuous for 30 to 60 minutes. Sedation follows the continuous application of hot or cold waters and they are not antagonistic by any means. Again we may have a condition in which there is a call for stimulation. Any condition of interstitial nephritis combined with cardiac lesions, which to your mind calls for the use of digitalis, strophanthus, spartein, or any of the cardiac stimulants, can be met promptly and efficiently by the brief cold sheet rub. In dilatation of the heart, when it is not compensating fairly well, and when as a part of the condition the urine is scanty, it is efficient also. One of the quickest means of securing a diuretic effect is that mentioned by Dr. Herrick —hypodermoclysis—the injection of normal salt solution. There is a better and painless method for obtaining prompt diuretic action—enteroclysis. The colon is flushed with a hot injection of two or three quarts of water, beginning with a temperature of 110 and raising it to 120 F. The long colonic flushing-tube is employed, the colon is filled and the water allowed to pass out again through the tube. After this colonic flushing with hot water, half a pint of normal salt solution is left in the rectum. This amount of solution will be retained, and in twenty minutes' time its action is marked both on the kidneys and on the heart. Dr. Baker has reported some experiments that he has conducted upon himself in this line, and he says there is nothing more efficient as a diuretic than these hot flushings, followed by a retention injection of half a pint of normal salt solution. It strikes me that the introduction into the rectum, after colonic flushings of hot water, of one or two drams of the citrate of potassium left in this water would be very beneficial. The physiologic action of the water, briefly applied, is stimulating. You know how closely the transverse colon and its flexures approach the kidneys; hence a direct stimulating effect of the hot water upon the kidney itself is obtained, also a reflex, stimulating effect on the heart. Take the cases of marked uremia, in which we have headache, cramps in the muscles, skin irritations, and possibly a tendency to drowsiness, coma, or convulsive symptoms, nothing can relieve that condition so quickly as the hot bath or pack for the purpose of diaphoresis. I hardly see the force of the remarks of Dr. Herrick regarding condensation of the blood and the leaving of toxic principles in the blood by diaphoresis. Have you ever observed that, by these hot baths, in a condition of uremia, the skin, supplementing the action of the kidneys, is capable of eliminating an immense amount of toxic material, and that the sheet will reek with the emanations of the patient after a forty or sixty minutes' pack? This should always be followed by the brief reaction sponge of cold water. Hydriatic methods applied in accordance with varying indications do not preclude by any means therapeutic application of drugs, but they must be considered valuable aids, and in many cases are far more efficient and valuable than any possible drug treatment.

DR. M. L. GOODKIND—There are some points in connection with the prophylaxis of nephritis that have not been mentioned either in the paper or in the discussion. Dr. Davis, in his remarks, referred to a toxic element in that class of cases hereditarily predisposed to nephritis, and I think that very frequently these patients are infected through the tonsils. In the class of cases predisposed to nephritis, the use of cold baths, as suggested by Dr. Burr, should be avoided. I have seen several cases in which nephritis was brought about by the constant use of cold sponge baths. Dr. Purdy mentioned the exclusion of a strict milk diet, in the terminal stage of nephritis, where the cardio-vascular disturbances are marked, on the ground that a greater strain is thrown on the kidneys. Von Noorden showed me a dozen cases in his clinic in which he practiced the same procedure as that suggested by Dr. Purdy, on the assumption that a fluid diet overstrains the heart, and for that reason he treats the broken-down heart by curtailing the amount of fluid and paying less attention to the kidneys in such cases. Another thing that Dr. Von Noorden mentioned at the time was, that there is a common misapprehension by the profession at large that red meat, or butcher's meat, contains more proteids and extractives that are injurious to the kidneys than white meats. The contrary obtains, he claims to have demonstrated, as the result of a series of experiments. In reference to the use of alteratives, I agree with Dr. Danforth, particularly in that class of cases in which there is by heredity a uric-acid tendency, and in which arteriosclerosis is present; also in the cases mentioned by Dr. Davis in which intestinal toxemia prevails. Several assistants of Kahler, working in his
so
years ago, demonstrated post-mortem the
in cases in which it was not suspected d
been no marked cardio-vascular chang

had not been the slightest trace of albumin, nor casts. Also a number of cases in which hyaline and granular casts, and a greater or less amount of albumin had been demonstrated *in vivo*, the patients dying of some adventitious trouble, showed not the slightest evidence of nephritis, so that the presence of a few granular or hyaline casts in the urine is not always pathognomonic of nephritis. Concerning albuminuric retinitis, and Dr. Herrick's prognosis of from twenty to twenty-four months as the extreme limit of life, I will say that there are certain cases in which we have the albuminuric retinitis of pregnancy and of scarlet fever, and yet these patients live for a great many years. These two classes of cases, therefore, offer a notable exception to the position taken by Dr. Herrick in regard to prognosis. I would like to ask Dr. Purdy whether he has had much experience in the use of morphin in edema of the lung, occurring in connection with nephritis, and whether he has found it to be a serviceable drug? Also, whether he has used the lactate of strontium in interstitial nephritis? Personally, I have used it without obtaining good results.

Dr. Frank S. Churchill—There is one aspect of the subject under discussion that has not been touched upon, and which, it seems to me, is of great importance. It should receive more attention than it has in the past. I believe we shall have to look for the solution of the cause of interstitial nephritis in the adult to an exhaustive study of the conditions existing in infancy and childhood which lead to the condition in which interstitial nephritis develops. Of course, that is a tremendous problem, and means an exhaustive examination of a large number of infants, beginning with the first day of life, and following them all through life up to the point in which they do or do not develop this disease. The magnitude of the problem is very great. Careful and repeated examinations of the urine from the time of birth up to the time nephritis has developed should be made. We ought to examine the twenty-four-hour amount of urine with a view to detecting the presence or absence of albumin, casts, sugar, and estimate also the solids of the urine. I have only reached the point of examining the urine of a number of children in a condition of health, and those observations I have already published.[1] These observations were made on the solids, the chlorids, phosphates and sulphates by the method suggested by Dr. Purdy, and also the amount of urea and the total amount of water. One of the most significant points brought out in these investigations was the small amount of water passed by these children. They were mostly of foreign parentage, but living in an asylum under American conditions of life. I could not find that these children had a smaller amount of fluid than children encountered in private practice. They passed a smaller amount of urine than is indicated by the results published by European and English observers among children, and following the subject up I was interested to see that the same results obtained among adults. The adults in America pass a smaller amount of urine than do the cases recorded by foreign observers.

Dr. Elliott alluded to the hereditary cases of interstitial nephritis, saying that these are apt to run a much more severe course than those in which there is no such heredity. I would like to throw out the suggestion, that in these cases this hereditary tendency possibly gains headway during the periods of infancy and childhood; and that exhaustive examinations of the urine of such children may show a condition of things which would perhaps put us on our guard and enable us to prevent or put off to a much later period the development of interstitial nephritis. But my chief object in speaking is to make a plea for a more extended and more exhaustive examination of the urine in children.

Dr. Edward F. Wells—I wish to call attention to two points of practical importance in this discussion. First in the management of edema of the lungs, life will often be saved by making the mouth and nostrils the lowest point of an inclined plane. This will allow the fluids to flow out of the bronchii, preventing the drowning of the patient in his own bronchial secretions. This should be employed in addition to medicinal treatment. Second, in cases of uremia, while introducing fluids into the system, and withdrawing fluids from the surface, from the kidneys and from the bowels, the blood may be actually washed and purified, in properly selected cases, by bleeding. This procedure, indicated in some cases, is also a life-saving measure.

Dr. Purdy (closing the discussion)—In replying to some of the points that have been raised in the discussion, I shall not attempt to answer them in the order in which they were given. I will first answer Dr. Herrick in reference to deaths due to affections of the heart in cases of interstitial nephritis. The statement I intended to make was that the majority of cases said to die from interstitial nephritis really die from some cardiac disease. A word of explanation is due here. I believe the statement to be correct. If we have no heart complication in cases of interstitial nephritis, they would go on and live longer than they do after the cardiac disease sets in. Although perhaps the disease is primarily in the kidney, death from uremia is more often secondarily than primarily due to the kidneys being worn out. When the cardiac complication becomes advanced it cuts off the renal function, the blood-pressure is lowered, and the urine in volume and quality is lowered; excretion is impeded, and the patient falls gradually into uremia or some complication of uremia, not directly from renal but from cardiac breakdown. If the heart-lesion had been recognized early and proper attention given to it, the patient's life would have been vastly prolonged. I have half a dozen cases on hand now in which the volume of urine is somewhat above normal, perhaps sixty ounces in twenty-four hours, with a specific gravity of 1005, 1006, or 1007, the total urea not exceeding 150 grains. I had two sisters in my office less than three weeks ago who are getting along with perfect comfort, apparently, on as near a non-nitrogenous diet as they can be put upon. When I saw these patients two years ago they were drenching themselves with enormous quantities of fluid, drinking gallons of water daily. Neither of them has any material cardiac complication. Cases of ordinary interstitial nephritis will run along almost indefinitely until cardiac complications set in and make substantial progress, then the patient will die without exception—not from renal, but from cardiac failure.

With reference to alteratives, I have not had very much experience in the use of mercury. To be frank, I am prejudiced against it. I have great faith in the iodids, and have used them a great deal. I believe, however, that their true action is as vasodilators. Perhaps I can best illustrate this by citing the case of a man of whom I have had some knowledge for over twenty years. For fifteen years he was in the hands of a well-known physician of this city, who gives alteratives freely. He kept this man on iodids most of the time for fifteen years, but did not modify his diet. What is the consequence? His kidneys are practically rudiments to-day. During the past two and a half years, while he has been under my care, I have never known him to exceed a hundred and eightly grains of urea a day. I believe the iodids saved his heart and prolonged his life.

I agree with Drs. Elliott and Danforth that much harm is done by giving an excessive amount of fluid. There may be cases requiring flushing of the kidneys for a time. I believe it is a good point to allow a patient three or four pints of fluid, say three pints each day; but sending patients to mineral springs is not good for the patients.

In regard to the diagnosis of interstitial nephritis, I was much interested in the remarks of Dr. Danforth. We all know that Dr. Danforth has made a careful study of casts. I believe there is much in what he has said; at the same time, a case of chronic interstitial nephritis sometimes becomes subacute; it has periods of acute tendencies. A man with interstitial nephritis may get some septic complication, some fever, causing slight diffuse nephritis, or, as Dr. Danforth expresses it, a catarrhal nephritis.

With reference to the visual disorders of nephritis, it must be remembered that we have a number of forms of amblyopia in nephritis. We have acute uremic amaurosis, which may come on in an hour, and disappear practically in six hours, due to uremia. The retinal-lesions are chiefly due to albuminuric retinitis, and to the hemorrhages into the retina. True, albuminuric retinitis is one of the late lesions of the disease, and the statement that patients do not live as a rule more than two years may be correct. But there are certainly exceptions to that rule. I have seen patients live over four years. I recall a case in Burlington, Iowa, under the charge of a local oculist there, which is now doing fairly well in his sixth year. But that is very unusual.

---

[1] Trans. Am. Ped. Soc., Vol. X, 1898.

The remarks of Dr. Davis as to the difficulties of carrying out prophylaxis are very pertinent to this discussion. It seems almost impossible to modify the habits of a man of fifty or sixty years of age, who has always been robust and strong. In short, the habits of a lifetime are almost unchangeable in such patients. When you consider that you have to pit your advice of half an hour against the habits of a lifetime, it is an exceedingly difficult thing to have a patient follow your suggestions as to diet and mode of life.

I quite agree with what has been said concerning laxative treatment, and, in fact, what little I suggested in the way of medication was coupled with advice in reference to diet, and the use of a saline laxative every alternate day. By the way, there is another point about the excessive use of water that I desire to mention. Where we have a hypertrophied heart, the heart taking up more space than it should in the thorax, the constant overfilling of the stomach with fluids is one of the worst things that can be done. It encumbers the heart's action greatly.

With regard to the remarks of Dr. Burr in reference to cold baths, I must say that I do not believe in them. A very important part of my treatment of interstitial nephritis is the care of the skin. I have seen many cases go along and do fairly well until they met with a chilling of the skin, which has precipitated a uremia and caused death. I have seen this take place so frequently that I have become afraid of cold baths and cold water. If we wish elimination by the skin, I do not think the hot pack, or hot water, is the best method of getting it. It stands to reason that evaporation from the skin is vastly more rapid in a dry than in a moist atmosphere. If you want to get diaphoresis in an active form, you can get it best by a dry hot-air bath. One of the first things I insist upon is that patients shall wear all wool next to the skin in this climate. The skin contains a large amount of blood; chilling the vessels will cause them to contract, driving the blood into the internal organs—the weakest organs get most of the extra flow of blood.

As to the use of opium in edema of the lungs, I think a single hypodermic injection of morphia with atropin will sometimes cut short an edema of the lungs. It is a dangerous drug to give in interstitial nephritis, unless it is restricted to a single dose, and time allowed for its elimination. The elimination of opiates is slow. If you give a patient a full dose of morphin or opium, who has interstitial nephritis in pronounced form, you will find that he will be under the influence of the drug much longer than a person whose kidneys are sound. If we use a diuretic, my preference is the citrate of potash, which, in cases of nephritis, is the only remedy that lowers the albumin in the urine. It does so invariably.

California Academy of Medicine.

San Francisco, June, 1900.

Dr D. W. Montgomery in the chair.

FRACTURED PATELLA.

Dr. Dudley Tait presented a patient 54 years of age, who, three years previously, was treated for a fractured patella. Treatment for 2½ months with splint and cast had left him with a painful, swollen and almost useless knee. Two years later he had opened the joint and found two small, porous, widely-separated fragments. Perfect approximation was impossible, even in extreme extension and after lateral incision of the quadriceps tendon and patellar ligament. The remnants of the patella were removed entirely shortly afterward, and the patient is now able to work, does not limp, and walks without the aid of a cane. He said that many have an exaggerated idea of the importance of the patella, which is merely a sesamoid bone. In the transverse fracture of the patella, without involvement of the peripatellar soft tissues, there will not be more than from 4 to 6 mm. of separation of the fragments. If, on the contrary, the lateral aponeurotic expansions are torn, there may occur a marked separation, especially in case of pressure from behind—hemarthrosis. Keen's suggestion of disinserting the patellar ligament would not have been of any service in the case presented.

Dr. G. E. Caglieri presented a young man whose patella had been fractured by falling, sustaining a transverse fracture. The morning following the accident he operated, making a horse-shoe incision. The joint was found filled with blood-clots, which were all removed by thorough flushing. The two fragments were surrounded by a silk ligature, passing it through the patellar tendon below and the quadriceps extensor tendon above. The result was excellent, the patient walking after four weeks. He said that the subcutaneous methods in fractures of the patella were not to be relied upon, and laid particular stress on the necessity of getting out all blood-clots and fragments of bone from the joint cavity.

Dr. Tait said that where there is distinct separation of the fragments and soft tissues intervening, the open treatment is always indicated. He advocates early intervention, as the resistance of the tissues is diminished by delay.

Dr. Henry Kugeler said that Dr. MacEwen wires or sews in all his cases, the main thing being to bring the fibrous tissue together. Most operators use catgut or silk in doing this, wire being not as frequently used. He said that he agreed with Dr. Tait regarding the necessity for immediate union, and that the point Dr. MacEwen makes in advocating the operative treatment in all cases is that fibrous threads fall in between the fragments almost invariably. Dr. Huntington said that prompt action in these cases is certainly the accredited one, as blood-clot forms a good culture-medium. In a recent case of his, in which high temperature and other septic symptoms developed, he aspirated the joint and found it was a streptococcic infection. The patient died, but had the joint been opened and cleaned out earlier, the result might have been different. Regarding the wiring of the fragments, he said that hard and fast rules can not be laid down, as opinion among authorities is very much divided. When the bones can be properly approximated the joint should not be opened. Scudder, of Boston, in a recent article, stated that simple fracture of the patella by the open method was justifiable, but he showed that after a given number of months, the results as far as function was concerned, were about the same as when treated without opening the joint. If that is correct, it certainly is no strong argument for dealing with an ordinary fractured patella by the open method. The procedure may be safe in hospitals; there can not be absolute immunity from sepsis when a joint is opened.

Dr. G. E. Caglieri said that under proper aseptic precautions in hospitals there was no great danger in properly opening any joint, and that he would no more hesitate to do so than to open the abdominal cavity.

Dr. H. M. Sherman said that the proposition of opening any joint was not analogous to opening the abdomen. Ideas are somewhat perverted by speaking of the synovial membrane. The wall of a joint cavity is composed of connective tissue, and there is no tissue in the joint hostile to infection like the peritoneum is. The joint is simply a space in connective tissue, and has not the same power to throw off infection, therefore we have to hesitate more in opening any joint than in opening the abdomen. In all joints, there is every tendency for infection to spread, no tendency for the focus to be walled off as in the peritoneum. The collateral features have to decide whether to open or not. When there are blood-clots in the cavity we can not very well get rid of them by means of the trocar. He had tried to devise a way of holding the fragments together, with only fair success, but good success as far as the result was concerned. His plan was to place a plaster-of-paris band around the joint, and then hold the fragments together with the fingers, by making firm pressure into the plaster until it thoroughly set.

Dr. Geo. F. Shiels said that the conservative opinion of never opening anything that can remain closed was the proper one. The method he liked best was [illegible] passing a [illegible] through the quadriceps extensor [illegible] and [illegible] mentum patellæ below, and holding [illegible] s th[illegible] position.

Dr. Dudley Tait said that he did not think Dr. Caglieri's case was presented with the intention of advocating the open method in treating all cases of fractured patella, as such a practice would prove dangerous, if not criminal, outside of a well-appointed hospital. In cases, however, in which there is great distention of the joint and extensive laceration of the peripatellar tissue, nothing will give such an ideal, sure, and rapid result as the method of encircling the fragments. This procedure is extremely easy and rapid, and should replace the old method of wiring in very many instances. It matters little what kind of union takes place. Good fibrous is as serviceable as bony union. Hence the result of treatment can not be accurately estimated by the X-rays alone.

THYROID SURGERY.

Dr. H. M. Sherman exhibited a thyroid gland which he had removed because of cysts. It had increased in size to the point of causing dyspnea and some tachycardia. There was considerable disfigurement, and it was for cosmetic purposes that he removed it. The removal was easily accomplished and he had no trouble with the recurrent laryngeal nerve. He left some portion of the right lobe to prevent the occurrence of myxedema. His principal object in reporting the case was to speak of a new drainage material that he had used, linen mesh, the material used in the manufacture of the linen mesh underwear, which has certain qualities which render it superior to gauze as a drain. The operation had been done after Treves, making a vertical incision in the median line with a transverse incision joining this at right angles dividing the muscular structures covering the gland, and making accurate end-to-end approximation of the same by suturing, after enucleation.

Dr. T. W. Huntington said that he had not found it necessary to divide the muscular structures. He uses the Kocher horse-shoe incision, which follows the crease in the neck, instead of the straight incision of Treves, and believes that it is the incision that will be followed in the future by most surgeons, by reason of the slight scar that results.

Dr. Henry A. Kugeler said that he saw Kocher operate a number of times at his clinic, and that he uses local anesthesia by Schleich's method of cocain infiltration. Regarding drainage in these cases he stated that McBurney uses strips of sterile rubber tissue, that acts well and is an excellent method, while some operators use wool thread wound up in wick.

MALIGNANT GROWTHS.

Dr. Dudley Tait showed a patient 55 years of age, who entered the French Hospital 14½ months ago with a malignant growth involving the pyloric region, the entire smaller curvature, and a portion of the greater curvature of the stomach. He had vomited all food for weeks previously and had lost 30 pounds. His condition was extremely cachectic, hemoglobin was 38 per cent. Gastroenterostomy was done with great difficulty, on account of the numerous adhesions, especially posteriorly. The patient soon gained 25 pounds and returned to work, but, for the past three weeks, he had presented symptoms of obstruction of the anastomotic opening. Palpation shows an adherent epigastric tumor and a series of nodules corresponding to several of the through-and-through stitch-holes. He proposed duodenostomy, and asked for suggestions from members of the Academy. He also exhibited a specimen showing extensive involvement of the genito-urinary tract. During life the patient had complained solely of a swollen epididymis, and had requested an operation, which was refused.

FORCEPS.

Dr. T. W. Huntington presented, before the Academy, the O'Hara intestinal anastomosis forceps and described their method of application.

Dr. Harold Brunn showed the LaPlace forceps and the Downes modification of the same.

AMERICAN.

1. Primary Carcinoma of the F [illegible] T[illegible] is paper is purely casuistic, adding one [illegible] to t[illegible] or so already reported of primary [illegible] the tubes. Mercelis gives the determi[illegible] th[illegible] of primary lesions and discusses [illegible] as been generally observed.

2. **Syphilis of the Brain.**—Eskridge first remarks on the occurrence of syphilis of the brain and its frequency, reporting the views of others in this regard without expressing a personal opinion. He says we can only say that the length of time after the initial lesions in which brain symptoms may develop is variable and indefinite, and we can not at any time state that there is no longer a danger of the brain becoming affected. He follows H. C. Wood in doubting whether any slight injury not causing inflammation can call out manifestations of brain syphilis in cases hitherto entirely free from intracranial infection. The direct effects of syphilis of the brain are few, the indirect effects are numerous. Only the specific lesions, those occurring directly from the disease, are amenable to specific treatment. The secondary effects are not specific in character and do not thus respond. Thus gumma, which is a characteristic typical lesion, carries with it numerous other disorders by compression and otherwise. Treatment, unless instituted early, is apt to be fruitless. He calls attention to the lesions that are produced by syphilis in the blood-vessels and other symptoms.

5. **"Floaters" in the Urine.**—From examinations and experiments with fifty samples of freshly voided gonorrheal infected urine Bernart concludes as follows:

1. The specific gravity of the urine is a prominent factor in the action of floaters.
2. The elements composing the floaters influence their action.
3. Their suspension at different depths in the urine is greatly due to some mechanical interference.
4. Upon filtration of the urine all but the very lightest floaters, those composed of flocculent mucus, will sink to the bottom of the beaker.
5. The action of floaters does not alone depend upon their composition or the specific gravity of the urine.

Since the difference in the length of the infection and its extent, and the influence of treatment, did not show a marked degree of difference in the results of the foregoing experiment, it is but fair to judge that some substance within the urine, which can be removed by filtration, influences the action of floaters and their diagnostic value.

7. **The Elements of Good Climate.**—The climate which Paquin thinks would be best adapted to the majority of respiratory troubles should be moderately high and dry and the air as pure as possible. It should be free from heavy winds, protracted rains and heavy fogs. It should have a soil favoring rapid drainage and evaporation; it should have a clear sky and sunlight for five-sixths or more of the time, and should neither be depressing when hot nor chilly when cold; and to afford the greatest measure of good it should have besides healthfulness, enjoyable scenery and surroundings and be unfavorable to homesickness. In any event the benefit depends on two factors: 1, rarefaction of the air; 2, dryness of the air. Mere altitude, however, combining these to a greater or less extent with each other, is not alone sufficient. The desiccating power of the air of high altitudes may itself have some disadvantages, and if as much good can be accomplished without the resort to a very high altitude it should be avoided. An important point is the blueness of the sky, which shows the pureness of the atmosphere. Moisture, which plays an important rôle, is to be considered. Heavy fogs are apt to be dangerous, but a light fog may be a cleansing agency and not be felt to have any disadvantages. Rainfalls are cleansing agencies, but if too persistent and heavy they may be damaging. The soil also must be considered. A mountain soil, not too porous, is the best. Sunshine and temperature are also to be considered, and the latter may be said to be from a climatic standpoint what it feels to one; that medium cold dry air and medium warm dry air are equally good, while the same degrees of temperature in a damp atmosphere are dangerous. He thinks the conditions which he has described are better met with for the year round in Western North Carolina than in any other part of the country. Not only the climate but the accommodations and food are elements in the success of the treatment and every case should be under the charge of a physician. This applies to the physician as well as the layman, since there is probably not a sufferer from tuberculosis whose judgment is trustworthy as regards his own case.

9. **Interscapulo-Thoracic and Scapular Amputation.**—Buchanan tabulates the cases known of total excision of the scapula at one operation for the preservation of the arm and also at two or more operations, and cases of excision of the scapula for tumor. He finds in summing up that interscapulo-thoracic amputation is primarily a very successful one, the mortality being only about 8 per cent.; 18.6 per cent. of cases whose post-operative history was definitely known were cured beyond the three-year limit. All cases operated on for enchondroma have remained free from recurrence, thus showing that these growths are comparatively benignant and do not warrant the conclusions drawn when they are included among the malignant neoplasms. Excision of the entire scapula for neoplasms has an immediate mortality of 17.3 per cent. and a record of 20 per cent. cured beyond the three-year limit in the malignant cases. Partial excision of the scapula for tumor, taking away less than the entire body, has an immediate mortality of 9 per cent. and a record of 33.3 per cent. of cures up to three years in the malignant cases. Partial excision of the scapula for tumor, taking away the entire body or more, has an immediate mortality of 26 per cent. and a record of 6.25 per cent. of cures. Notwithstanding these favorable results in total excision he does not hold it admissable to remove the entire bone, even in malignant cases, if less will possibly suffice. In conclusion he adds a note on the recent monograph of Picque and Dartigues and a paper by J. William White, who has reported cases, also some further data in regard to cases included in this paper.

11. **Rennin.**—The following are the conclusions of Coriat's article: *Action of Rennin in Digestion.* 1. The casein of milk can be digested by both pepsin and pancreatin, without being first coagulated by rennin. 2. When, however, rennin is present in order to precipitate the casein, the amount of digested proteid or albumose-peptone produced by the proteolytic enzymes above mentioned is greater in every case. 3. The presence of rennin is necessary to secure a more rapid and energetic casein digestion. 4. This increased peptone production, due to the presence of rennin, takes place in both acid (pepsin) and alkaline (pancreatic) media. *Action of Rennin on Coagulation.* 1. Combined HCl, when equal in bulk to one-tenth or less of the milk used, does not coagulate milk, even after prolonged action. 2. Combined HCl, when it exceeds one-tenth of the bulk of milk used, coagulates with rapidity, although not as rapidly as when HCl is free. 3. Free HCl, alone, coagulates milk. 4. Rennin coagulates milk without HCl being present, but when it is present in a combined form equal to one-tenth or less of the bulk of milk used, coagulation takes place in a much shorter period of time. 5. The presence of acid-albumin hastens coagulation by the enzymes. 6. Coagulation time decreases steadily, as greater amounts of absolute rennin are present. 7. Vegetable enzymes coagulate milk in a way which compares very favorably with rennin. 8. Coagulation with vegetable enzymes takes place under the same conditions of temperature, acidity and amount as rennin. 9. Enzymes exist in the plant kingdom, which have an action analogous to that of rennin.

14. **Lupus Erythematosus.**—In the first part of this article, the clinical portion, Fordyce discusses the relations of lupus erythematosus to tubercle, and seems to favor the theory that it is due to the toxins from Koch's bacilli. Three cases are reported which he thinks are suggestive in this direction. In the second portion of the article Holder discusses the pathology, giving illustrations of the microscopic findings. He thinks that if there is one thing absolutely known about the disease it is that the Koch bacillus is not present in this lesion; it is not true tuberculosis of the skin. No case has ever come under his own personal observation that shows the large percentage of tubercular antecedents given by the French observers. He concludes that everything seen in the microscope points to the fact that lupus erythematosus is a disease in which the blood-supply is interfered with. The normal capillary pressure is raised, but the cause is open to further investigation. Of the two phenomena that are characteristic of the early lesion he is inclined to place the infiltration secondary to a capillary

obstruction in the height of the erythema, but admits at the same time that it may be an effect and not a cause of connective-tissue change. He recommends to pathologists and dermatologists the use of Unna's acid orcein in lupus erythematosus.

15. **Heart Disease.**—Brannan reports a case of undoubted heart disease with obscure symptoms, which he discusses. The principal feature of the disease is, he thinks, the conduction of mitral regurgitation murmurs directly to the chest wall above the so-called pulmonary area. The diagnosis of mitral disease is reached by a sort of exclusion process in this case.

17. **Cancer.**—Warren's address covers the whole subject of the investigation of cancer, and he concludes that, so far as we have been able to ascertain by our studies, the question as to the parasitic origin must be considered as yet not proven. He thinks that it is only by long and patient research that we will be able to unlock the secret of this problem.

21.—See also No. 61.

24 **Tendon Transplantation.**—Townsend reviews the literature of tendon implantation in the case of deformities of the hand, and adds cases of his own to those which he has found to be published elsewhere. He thinks the reports of these cases show that we have at our command an operation which will do away with the necessity of the physician telling the patient that amputation is the best thing to do with a case of drop-wrist following cerebrospinal meningitis. It is important to thoroughly investigate the muscles of the hand before operation; and to get good results we must ascertain their electric reaction and their general functional capacity. It is advisable to suture tendons only that have power left, if we expect them to do active work in the future. A careful study of the muscles will tell us which one to transplant and how it can be best attached. He gives some details of the method of transplanting and discusses the probability as to the best results from operating on the tendons of the flexors and extensors respectively.

25. **Artificial Feeding of Infants.**—According to Bell, condensed milk is the most pernicious article in the feeding of infants and never a suitable substitute for mother's milk. He describes the methods of modification and finds that too great excess of proteids is especially damaging. The carbohydrates also differ. The different formulas and methods are discussed. One of the most serious problems is the difficulty of securing pure cow's milk for the modification. He suggests careful rules in regard to the care of the cows, looking after their health, frequent examinations of the milk, thorough washing of the udders, etc., and the milking being done in a room that is used for no other purpose and kept scrupulously clean. The great desideratum is a thoroughly competent and educated dairyman, as a high order of intelligence would be required to keep a model dairy.

26. **Subphrenic Abscess.**—Baldwin reports two cases of subphrenic abscess following appendicitis, and calls attention to the importance of the recognition of these cases. If it is not recognized and not treated surgically the mortality is very high.

27. **Petroleum in the Treatment of Phthisis.**—The petroleum products known as vaselin, terralin, etc., are suggested by Robinson as valuable agents in the treatment of phthisis. The material which he has used has been a perfectly refined product. and he gave it in 2-dram doses, four times a day for a period of from three to six months, in every instance with increase in weight, improvement in health, strength and feeling of well-being. The gain was from 5½ to 23½ pounds, and there was no other treatment which could be held responsible for it. The treatment gave no discomfort in any case, as the material is absolutely indigestible and unchangeable in the intestinal tract and passes through unaltered. Fermentive and putrescent changes were controlled and normal functions along the entire tract were re-established. The intestinal toxins were either not formed or were carried off by the petroleum. Indican and sulphates disappeared from the urine. The effect he considers entirely mechanical. Petroleum has also the property of being an ideal solvent for many remedies useful in the treatment of phthisis, such as creosote, the fixed oils and most volatile oils, alkaloids, and many chemicals. It is a solvent of iodin, sulphur, betanaphthol, naphtalin, menthol, etc., and by the addition of a little ether, chloroform, or oleic acid its power to dissolve is greatly increased. Its use in phthisis is by its mechanical action and its association with other remedies. It is the best medium for the conveyance of remedies by nebulization to the throat and bronchial tubes. It is an ideal remedy for the cure of all forms of constipation, and for treatment of tuberculous diarrhea.

29. **Infantile Amaurotic Family Idiocy.**—Claiborne reports a case of this disorder and discusses the condition. The patient was not a Jew. It differs from those previously reported in this respect, and general tuberculosis was also found at autopsy, with also a tumor of the corpora quadrigemina, with associated ocular symptoms. This suggested to him that special attention be called to tuberculosis as a probable general etiologic factor and to the corpora quadrigemina as the seat of a possible causal lesion. In conclusion he suggests the query whether we are justified in assuming the symptoms of this condition to indicate a definite morbid species or not.

33. **The Serum Treatment of Tuberculosis.**—Spicer reports a case of apparently rapid tuberculosis in a young woman with a bad family history, in which the prognosis was given as bad, but serum treatment was attempted as a last resort, the material used being the antiphthisic serum T. R. The initial dose was 8 minims, hypodermically, afterward increased to 15 minims. One hundred and four injections have been made in all during the seven months which have elapsed since beginning the treatment, and there are now no râles, no night sweats, and no cough, but she tires easily on exertion. Of the three other cases treatetd, in which only about 35 injections were made, two improved and one died. The inferences he deduces are, that the treatment should be begun early, it should be continued for a long time, and it should not be used in hopeless cases.

34. **Degeneracy Stigmata.**—Kiernan's article deals especially with the history of Lord Byron.

36. **Inebriate Criminals.**—The inebriate criminals which are described by Crothers are those that form the most troublesome class of asylum inmates. He thinks they require special treatment and should be classified in different groups and governed by strict military discipline in which labor is part of the treatment, and this be continued for months and years. If this class can be removed from the inebriate asylum the percentage of recoveries would be largely increased.

37. **Gynecology and Neurology.**—Hughes speaks of the inter-relation of gynecology and neurology, calling attention to the points where too much has been made of certain peculiar phases of functional hysterical diseases, etc. He thinks that too much attention has been called to the sexual function and its organs and less than should be to nervous symptoms in the gynecologist's practice. The psychic element is one that must be counted also in many cases, and special care exercised as to sexual and gynecologic suggestion in neuropaths.

38. **Military Psychiatry.**—Hughes discusses the conditions involving the mental health of the American soldier and pleads for psychiatric expert treatment in military posts. His paper concludes with some letters from the surgeon-general and deputy surgeon-general of the United States Army showing that the number of insane cases among the American soldiers in the Philippines is not apparently greater than the proportion that occurs ordinarily in time of peace.

40.—See abstract in The Journal of June 2, p. 1413.

41.—Ibid., June 2, p. 1414.

42.—Ibid., June 2, p. 1414.

43. **Color Perception.**—Holden and Bosse have experimented, using colored ribbons, and worsteds, with children at various ages to ascertain their color preference and color sense, and give the results. They found that these support by analogy singularly well the Gladstone theory of development of color perception in the human race, so that this may have a certain value, though we must go farther down in the mammalian scale than to primitive man to find the beginning of color perception. They found that all infants choose colors

from the red end of the spectrum rather than the blue, but as the psychic development proceeds and the child becomes more distinguished from the animal, and mental processes dominate the earlier more physiologic reactions, we find first an indifference to all colors and a little later as a rule a dislike for the exciting reds and yellows and a preference for the less exciting colors of the blue end of the spectrum. At the age of eight a blue or violet preference is almost universal, but red has begun to advance again from the lower end of the scale. In adults, as others have found, the end colors of the spectrum, blue, violet and red are the preferred ones. They find that untrained children as early as the third and fourth year, with the exception of those that were palpably color-blind, match fairly saturated colors with great accuracy, blundering only usually in confounding blue with violet. With worsteds of less saturated hue, the results are very different and a tendency to match according to luminosity rather than hue was frequent. When the child is 5 or 6 years old this tendency to match according to luminosity was lost and the matching even of tints and shades is done usually with considerable accuracy, though there still may be a tendency to confound blue with violet, which is outgrown only later.

48. **Retraction Movements of the Eyeball.**—The following is the summary of Wolff's paper: Retraction movements of the human eye have been described in only seven cases, to which five are herewith added. The retraction movements never occur as a solitary symptom, but always form part of the same group of clinical symptoms, producing a well-defined clinical picture, whose characteristics are as follows: The condition is always congenital. Retraction occurs during attempted adduction, which may be absent or present, but is always less than normal. Retraction is accompanied by narrowing of the palpebral fissure. Partial or complete paralysis of the external rectus of the retracted eye is regularly present. Some cases present a moderate constant retraction and narrowing of the fissure even in the primary position. In these cases attempts at abduction produce a propulsion of the globe and widening of the fissure. When the retraction is considerable the cornea is turned upward in some cases, downward in others, even when the fellow eye makes a purely lateral movement. This is due, probably, to resistance made by the optic nerve. Two explanations are offered to account for the retraction; the faulty insertion and the fixation theories. Though the former is supported by some evidence, the latter accounts more satisfactorily for all the symptoms and is even better supported by evidence. Surgical interference may benefit some of the cases. There is reason to believe that the retraction movements are often overlooked and that these cases are not so rare as the small number reported would indicate.

59. **The Relative Value of Vaginal and Abdominal Operations.**—Richelot concludes from his consideration of the subject that: "1. In uterine fibromas, the two methods, abdominal and vaginal, have an equal value; each one has its indications, but the upper route is the most often indicated, and vaginal hysterectomy can no longer to-day claim the same superiority as formerly. 2. In cancer of the uterus, vaginal hysterectomy is superior to every other method; it permits us to obtain, in a proportion of not less than 10 per cent., prolonged survival, and even cures which seem to be final. The best operation is that which precedes cancerous infiltration, and not that which pretends to pursue it through the pelvic cavity. Abdominal hysterectomy is an extra resource in a very limited number of cases, but, applied deliberately to invading cancers, it is an imprudence, and for limited cancers it is an illusion. 3. In pelvic suppuration the conduct to be used is variable and responds to complex indications; improvements of technique have given a great value to the suprapubic method, which ought to be preferred in certain cases. But most frequently, when the surgeon is sure of his diagnosis, if he wishes to give his patient the greatest security and the least suffering, vaginal hysterectomy is the method of election."

61. **Attitude of Fetus in Utero.**—Zinke thinks that too little attention is given in the instruction to abnormal presentations or the position of the fetus *in utero* and in this article he calls attention to the method of external manipulation to determine the position. He mentions that in nine cases out of ten the attitude of the fetus can be ascertained during the last ten weeks of gestation by external means of diagnosis alone, viz., inspection, palpation and auscultation. By the first of these we determine the contour, size and position of the uterus and frequently also the fetal movements. By the second we locate the movements, the head and back of the fetus. By the third we find the site where the impulse of the fetal heart can be heard with greatest intensity. He examines his patient in the recumbent position and for convenience divides the abdominal surface into four quarters, the lines crossing at the umbilicus. The paper is illustrated with schematic drawings showing the different positions of the fetal heart, etc., in the separate positions. See also title 21.

67. **Enucleation of the Eyeball.**—The conditions requiring enucleation are given by Lauder as follows: 1. Intraocular malignant tumors. 2. The presence of a foreign body impossible to be removed. 3. Injury to the eye precluding possibility of recovery; such as rupture of eyeball from the result of a blow, though recovery may be possible even in some of these cases. 4. Where there is a condition of epiocular malignant tumors and also orbital tumors, which threaten life, but which can not be removed without destroying the eye. 5. Cases of disease which cause intolerable pain and which are incurably blind. This condition is sometimes met with in irido-cyclitis, phthisis bulbi and in glaucoma absolutum. In this case operation should be performed only as a last resort after every other less radical operation has proved fruitless.

72.—See abstract in The Journal of June 2, p. 1414.

76. **Erysipelas.**—According to Carrier, erysipelas is an acute, infectious process of the skin and mucous membranes, self-limited, and always due to the Fehleisen streptococcus. The contents of the vesicular or bullous lesions are serofibrinous in character, and when pus occurs it is the result of infection by a pyogenic germ added to the erysipelas, in other words, a complication. Internal medication exerts but little influence over the course of the disease and should be reserved for emergencies. The dietetic management of the disease is of the greatest importance, and forced feeding furnishes the best means of combating it. Little is to be expected from the actions of germicides when applied locally. Protection from the atmosphere will relieve the distressing subjective symptoms. From the known influence of cold upon the life of the germ, it follows that a reduction of the bodily temperature is of prime importance, and is best accomplished by cold bathing while the continuous application of the ice-bag upon the affected surface is the best of local applications. Where sufficient pressure can be applied to the lymph-channels to interfere with the lymph-current, spread of the lesion might be controlled by its use. Isolation, a cold room, and plenty of fresh air, in addition to the above, furnish the best treatment for the process we have been considering.

77. **Tuberculosis.**—This paper by Evans is largely an attack on Koch, whom he credits with having taken the fruits of other earlier discoveries without credit, making himself as he says a literary anastomosis, whereby he has united to himself all previous experimental knowledge regarding this bewildering subject. The general point of his article is that consumption is still very little understood and that the men most of all in error are the ones who believe it to be a contagious disease.

79. **Motion of the Lymph.**—The argument brought forward in this article by Herz is that the lymph carries the nutrition rather to the tissues than the blood. It can not be followed in detail nor abstracted adequately and fully here.

90. **Ozena.**—The principal point of Holinger's paper is that ozena is mainly due to excessive wideness of the face and nostrils. With this there may exist also a metaplasia of the mucous membrane of the nose which is not explained.

92. **Hernia in Children.**—Bartholomew holds that no child should be allowed to reach puberty with an uncured hernia. If the truss treatment diligently followed should fail, operation should be undertaken. Hernia in children in most cases is congenital and of the oblique inguinal variety, and the open-

ing is easily closed and less liable to recur than in the adult. About 8 per cent. of them are not amenable to treatment by trusses. Trusses are not well borne by children and are difficult to manage, and after three years of faithful treatment nearly 50 per cent. of cases are still uncured. Hernias thus cured frequently relapse after adolescence. Generally speaking, the best time to operate is just before the child assumes the upright position. Mechanical treatment should not be persevered in after this unless there is marked diminution in the size of the hernial opening. The indications for the radical cure of hernia are: 1, cases complicated with hydrocele; 2, irreducible, incarcerated and strangulated hernias; 3, cases in which the hernia can not be kept up by a truss without much discomfort to the patient; 4, cases unable to obtain the care requisite for success, and 5, cases in which mechanical treatment has been faithfully tried without results.

97. **Nirvanin.**—The paper by Floeckinger gives the results of experiments which he sums up as follows: Cocain has a ten-fold more toxic action than nirvanin in the same dose. Disturbance on the side of the central nervous system and toxic symptoms in the employment of nirvanin in the stated doses (0.1 to 0.5 gm.) occurred in not a single case. Nirvanin has an antibacterial action which is entirely absent in cocain. The analgesia from nirvanin lasts longer than that with cocain and it also appears earlier. We can absolutely exclude a nirvanin habit. The burning pain is only present in nirvanin injections with the too rapid flow of the injection fluid. The after-pain which is always present in cocain injections is absent in the correctly performed nirvanin injections. In the major operations he has usually employed injections of morphin one-half hour before the operation, which had a quieting effect on the organs, the dose is from 1/8 to 1/4 gr.

100. **Cesarean Section.**—Williams enumerates the advantages of Cesarean section as compared with those of symphyseotomy; the maternal mortality is no greater and the infant mortality *nil;* the operation is more satisfactory from the surgical point of view; there is the certainty of being able to complete the operation at once and the great advantages afforded in the after-treatment, by the clean abdominal incision, instead of a wound at the pubis requiring drainage, not to speak of injuries to the soft parts. There is no necessity for prolonged catheterization, and the patient is spared the long convalescence entailed by symphyseotomy. He believes that the old absolute indication for Cesarean section should disappear and instead of being placed at a conjugate of 5.5 cm. it should be extended to 6.5 cm. provided the child is alive. Questions as to sterilization in cases of deformity of pelvis, and craniotomy are also discussed. He thinks that induction of labor six weeks before the expected confinement is advisable in case of multiparous women with normal pelves who have given birth repeatedly to large children which have died during labor. By this method he thinks we will be able to save the mother and child and have better results than with Cesarean section as far as the mother is concerned and probably as good with the child. In advising Cesarean section he does not mean to say that it should be attempted by those without experience in major surgery. The average case is simple, but in a minority of cases the uterus may fail to contract and hemorrhage threaten. In such instances the only resort is to remove the uterus, and unless the physician feels competent to do this he had better not attempt Cesarean section.

106. **Gynecologic Mistakes.**—The mistakes mentioned by Hayd are, the useless operations performed for the relief of pain otherwise relievable; the useless and reckless curetting done in many cases of mild endometritis; the neglect and mistreatment of cervical lacerations, etc.; the uterine treatment for ureteritis and rectal troubles; the error of mistaking neuralgic ovarian disorder for organic disease; the misuse of the uterine sound and uterine applications; the harm done by galvanic electrode and pessaries. Although the cry is that there is too much operating done now, yet in the face of this just criticism he believes that most of the symptoms producing definite and discoverable lesions of women are cured best and quickest by operative measures and the error in the past was in not pushing surgery far enough.

108. **Medical Treatment of Cataract.**—The testimony of the laity and some physicians as to the value of certain drugs, such as cineraria for cataract, induced Grove to give it a trial. He has found it absolutely worthless. He does not have faith in any medicinal treatment of cataract. Massage may do harm as well as good and the claims of galvanization have likewise no reliable foundation.

111. **Surgery Among the Insane.**—This latest of Hobbs' papers on this subject enumerates the difficulties and advantages of surgical operations in the insane. The former are detailed as follows: 1, difficulties of diagnosis due to lack of reliable subjective symptoms and the frequent anesthesia in these cases; 2, difficulties of examination due to their mental condition and delusions; 3, difficulties of anesthesia, and these patients are especially sensitive to chloroform, which is liable to produce uncomfortable symptoms; 4, difficulties of preparation for operation, and 5, difficulties of after-treatment, both depending on the mental condition of the patients. On the other hand there are the advantages of little or no shock, the possibility of enforcing proper care in the after-treatment and the easy recovery from ether narcosis. While he does not operate for the relief of the mental condition, he again claims he has most remarkable results in the way of cures of insanity. He divides his patients into two groups: the inflammatory group, in which the improved ratio of recovery is 17 per cent., and the non-inflammatory group of cases, in which the ratio of improvement is somewhat less but still remarkable.

131. **Losdorfer's Bodies.**—Neudörfer describes as a new discovery the findings by Dr. Losdörfer, of Vienna, of certain germs or bodies in the blood of syphilitics. There is a peculiar resemblance between the name of this new discovery and the old long-known Lostorfer corpuscles, which are not mentioned in his history of preliminary work along this line in the beginning of his article. He thinks this new discovery is a long step in advance in the solution of the question as to the origin of syphilis.

140. **Suprapubic Cystotomy.**—The advantages of suprapubic cystotomy are, according to Nuzum: 1. The ease and safety, under modern antiseptic procedures, with which it can be performed. 2. The operator has full and easy view of the field of operation. 3. The operation is adapted to any disease or condition for which a lithotomy should be made. 4. It is far less dangerous than any cut into the bladder through the perineum. 5. You go through parts less richly supplied with nerves, blood-vessels, and important structures. 6. If a fistula remains, it is not constantly leaking, and with a properly adjusted urinal, the patient can pursue his occupation with very slight inconvenience or discomfort. 7. The ease with which a permanent fistula can be maintained when desired.

150. **Treatment of Uterine Fibroids.**—Smith considers the subject of the surgical treatment of uterine fibroids and concludes that curettage is the best palliative method of controlling hemorrhage though it fills no other indications. Ligation and resection of uterine arteries is advisable and should be employed with small tumors for the purpose of [illegible] arresting hemorrhage and growth. Castration, while yielding good results in some hands, notably Tait's, has fallen into disfavor, chiefly on account of its uncertainty and the [illegible] dangers of the operation. Myomectomy is an [illegible] election in all women under 45 years of age when it is possible by this means to restore normal function, and [illegible] to arrest the growth by ligation of the arteries [illegible] cases. In attempting myomectomy the operator [illegible] be prepared to resort to hysterectomy [illegible] Hystero-myomectomy is and always will be [illegible] dealing with these growths.

151. *Panhysterectomy.*—Rankin gives [illegible] technique of hystero-myomectomy and [illegible] paring their advantages and disadvantages [illegible] latter does away with many of the [illegible] methods, and should be preferred.

152. *Compound Fractures.*—[illegible] ance of early intervention in [illegible] most care as to the asepsis [illegible]

would first remove all foreign bodies, using hot water and soap, followed by disinfection, and flushing with large quantities of bichlorid solution and later sterilized water. Drainage should be placed in the most dependent part, as the vis-a-tergo action expected of gauze drainage is unreliable. Immediate amputation in cases involving the long bones need only be considered when it is a question of the patient's general condition being such as to undergo prolonged confinement in bed or to perfectly resist infection. Amputation, after traumatism and fractures completely destroying the circulation of the part, will demand such treatment as indicated in each individual case.

162. **Commissions by Specialists.**—Lanphear deals with the ethical propriety of a division of fees between the specialist and general practitioner. His conclusions are that no commission should ever be paid by the specialist for business simply referred or for ordinary consultation. No division of the fee should be thought of when the patient is taken to the specialist for consultation and operation. A division of fee is justifiable and honorable whenever the family doctor accompanies the patient a long distance and the patient can not or will not pay more than traveling expenses and the specialist's charge. It is also justifiable when the family physician is put to much trouble or loss of time in inducing the patient to submit to a specialist's treatment and the patient will not pay the doctor for his services. A division of fee is proper when the specialist operates and the physician assists and attends to the after-treatment. Division of the fee is also justifiable when the specialist and doctor treat the case jointly, as there are a large majority of people who will not pay two bills.

Use of Borax and Formaldehyde as Preservatives of Food. W. D. HALLIBURTON.—The attention of the author was called to the use of antiseptics as food preservatives, especially boric acid and borax, and formaldehyde. His experiments have led him to condemn them for such purposes. He does not find that boric acid itself has much effect on the digestion, which is probably partly explained by its insolubility, but borax, which has been used considerably in the compound, glacialin, a mixture of boric acid and borax, has a decided effect on the rennet activity in the stomach. The proportion of 1 part to 1000 of milk completely inhibits rennet, and a smaller proportion will delay its action. Formaldehyde, which is one of the most efficient of antiseptics, disintegrates the blood, and is irritating to the skin, and hardly can be less so to the much more tender mucous membrane of the stomach. His experiments were made to test the influence of formaldehyde on gastric digestion of proteids, and showed that .5 per cent. of formaldehyde rendered gastric digestion almost impossible, and .05 per cent. considerably delayed it. The influence on pancreatic digestion of proteids was similar and even more striking, while the action on the pancreatic digestion of starch showed that the addition of a .2 per cent. solution of formaldehyde increased the digestive time from one to three minutes. The action of two drops on the rennet-curdling of milk showed the same action—in some cases complete inhibition on the action of the ferment and in all cases delay. He says the proportion in which formaldehyde is stated to be used in milk is, roughly, 2 drops of the commercial 40 per cent. formaldehyde solution (formalin) per ounce of milk, and a much smaller dose than this has a decided effect.

Seventy-Two Consecutive Cases of Removal of Goiter by Operation (Extirpation or Enucleation). JAMES BERRY.—The author reports the results of extirpation and enucleation in 72 cases of goiter. By extirpation he means the removal of a portion of the thyroid gland with its capsule; by enucleation the removal of localized tumor, a cyst or adenoma within the gland. The necessity for operation depends on the effect in embarrassing respiration of the growth, and he does not consider deformity alone a sufficient cause. Dyspnea almost always demands operation and the worse the dyspnea the more urgent the demand. In cases of malignant tumors, however, tracheotomy affords too often the only means of giving relief. There are two kinds of goiter that are especially dangerous to life, owing to their great liability to cause sudden and dangerous dyspnea. One is the rapidly growing parenchymatous and, of course, bilateral goiter occurring at the age of puberty. In such cases dyspnea may come on so rapidly and suddenly as to cause death within a few days or hours. The other dangerous variety is that in which a unilateral tumor is situated low down in the neck and tends to become jammed in the upper opening of the thorax. By being suddenly displaced or by internal hemorrhage such tumors may cause very serious symptoms. Unilateral goiter above the sternum has very little tendency to cause serious dyspnea. Small tumors at the back of the gland are not uncommon and may cause pressure symptoms and yet be difficult of diagnosis. In local operation he prefers local anesthesia as safer and more convenient, saving the patient moreover from the distressing retching and vomiting, and it also facilitates healing of the wound by avoidance of venous hemorrhage. The operation is not necessarily a painful one with local anesthesia; the only painful parts are the beginning and end, the incision of the skin and sewing it up. The single oblique incision along the anterior border of the external membrane is decidedly the best for large goiters, and where plenty of room is desired. Complicated, angular, or T-shaped incisions are scarcely ever necessary. The median incision is chiefly useful when it is uncertain which lobe is to be removed. All longitudinal and oblique incisions have the disadvantage of making an ugly scar in young persons; in middle-aged or old persons this is of less importance. The transverse incision does not give the operator nearly so much room. The operation of enucleation is done as quietly and deliberately as possible, all large vessels being tied before cut. Special care must be taken not to wound the recurrent laryngeal nerve; it is better not to disturb it by dissecting it out. Frequently he cuts through the goiter near the trachea after it has been isolated from the other parts. The capsule and small part of the goiter near the trachea are thus left to protect the nerve. He has but little to say as regards the details of enucleation; the chief difficulty is in recognizing the thin layer of altered gland tissue that covers the tumor. The incision should be carried through this and no farther. He attaches no importance to the removal of the tumor in unbroken condition. His results, some of which are illustrated and all of which are tabulated, give a mortality of three deaths in seventy-two cases, which he thinks is not unfavorable, considering the fact that these cases were formidable ones. One death was from chloroform, and one of the patients had also valvular heart disease. No deaths occurred from his enucleation operations. The ultimate results have all been good, and since the paper has been written he has operated on 20 more cases, bringing the total up to 100.

Degeneration of the Neuron. FREDERICK W. MOTT.—In this third lecture the author discusses the chemistry of degeneration and the chemistry of Marchi's method. He suggests the possibility of autointoxication due to choline formation from nervous degeneration. He assumes that a decomposition of the myelin of the proteid matter occurs, and that it escapes into the cerebrospinal fluid and thus into the blood in larger quantities than can be disposed of by oxidization, where its accumulation may produce autointoxication. This might account possibly for some of the symptoms of paresis. Choline is not a powerful toxic substance like neurin, which may also be produced under special conditions such as the existence of micro-organisms, and have its effect. There are two forms of degeneration, he says in conclusion, that may react to the Marchi stain: 1. Secondary Wallerian degeneration due to interruption of the axon when it is cut off from its cell or origin; fibers which have their cells or origin above the lesion degenerate downward and are recognized by the black-stained products of degeneration mapped out in definite areas. 2. Primary degeneration due to an altered condition of the blood and lymph caused generally from an introduction or generation of poisonous substances, insidious in origin, progressive and generally fatal. They are influenced by hereditary or acquired tendency to nervous degeneration, and election of the particular system or systems of neurons not only constitutes definite growths of clinically definite disease, but also constitutes definite groups of physical phenomena, which admit of classification into definite diseases, and also shows that certain poisons have elective affinities for particular systems of the neurons, but this election may also be determined by occupation and habits causing stress on some particular system of neurons, or vascular conditions may lead to circulatory degenerative changes determining the early appearance and more rapid degeneration changes in some parts of the nervous system than in others. Thus certain portions of the brain should show more atrophy and degeneration in paresis than others, the left hemisphere for example.

Present State of Our Knowledge Regarding Visual Sensation. R. Marcus Gunn.—The state of our knowledge as regards the sensation of sight is reviewed by Gunn, who notices first the nature of the stimulus. The term "ether wave" must not be held to imply any actual movement in the ether, but rather an influence and rapid periodic change of some of its properties. The theory now held in regard to the vibration of ether is that they are electro-magnetic. The human retina is influenced by a comparatively short part of the entire scale, corresponding to what may be called an octave. The shortest visible waves are approximately half the length of the longest, while on either side of these there are several octaves of invisible waves. There is no real distinction between heat and light waves. The phenomena produced by light in the living cells without visual function are: 1, movement of chlorophyl corpuscles; 2, chemical activity in the chlorophyl-containing cells; 3, the contraction of protoplasm. To these we may add phototaxis, which means the position or motion of free cells in relation to light. The general characteristics of a visual cell are: 1. The end of the cell corresponding to the cuticle has usually a rod-form prolongation. 2. The opposite end is either directly continued as a conducting fiber or is connected with a ganglion cell. 3. Pigment is present in the light percipient cell, or in a distinct or closely related cell, often in both. The arrangements in vertebrates are noticed. The action of light on such cells consists in the movement of pigment and swelling of the pigment-cell processes. There appears to be an oxidization process accompanied by a substitution of an acid for a previous alkaline reaction, which seems to be communicated to the rods and cones, and varies according to the wave-length. There are also with the action of light, besides this particular visible purple reaction, certain movements of the cones themselves and the effects on the visual and non-visual cells are on the whole strikingly similar. Very recently Waller has brought forward evidence showing that the light effect upon the fresh leaf is also accompanied by an electrical change, thus completing the parallelism. The conduction of impulse requires the nervous apparatus and nerve impulse, which can not be identified with the electric excitation in the visual cells themselves. The author discusses the physiology, where known, of this process. In the lower animals the fundamental idea of vision seems to be to connect it with muscular action in a protective way, and in finding food. He also mentions where changes in the color under the influence of the surroundings is shown in certain animals. As we go higher in the animal scale we find the visual fibers passing to the visual area of the cortex, but whether this is the seat of visual impression or merely a stage in the path to yet higher centers is not absolutely known. As regards our recognition of the conducted impulse we have two distinct sensations—color and brightness—both influenced by differences in the wave colors and wave lengths. Of these two sensations there is reason to believe light perception the more primitive, and that the rods are the elements concerned in this appreciation. It does not follow that the cones are functionless in this regard, but it is presumable that their office is the recognition of differences in stimulation associated with variations in the wave lengths recognized as colors.

Contagious Catarrh or Roup in Fowls, and Diphtheria in Man. J. Gordon Sharp.—The writer first distinguishes between gapes and roup, the former being due to a nematode worm in the windpipe, the latter presumably a bacterial disease which closely resembles diphtheria in its clinical features. A microbe was found which could not be distinguished from the Klebs-Loeffler bacillus, but it does not seem to transmit the disease to those handling the fowl. His conclusions are stated as follows: 1. Roup, like diphtheria—including the somewhat indefinite term "croup"—varies in its malignancy, sometimes being mild with only one or two deaths in a large hen-run, while the next epidemic may almost clear out the whole coop. 2. The disease does not appear to be transmissible to man, for those handling the affected birds without any precautions do not suffer from any disease resembling diphtheria. 3. Paralysis was, according to his observations, absent in roup cases. 4. The disease is evidently a highly contagious catarrh and may correspond to the *morve* or fowl glanders of the French. 5. Roup probably differs entirely from "fowl diphtheria," so-called. 6. As we have already seen, bird-fanciers distinguish between a "dry roup" and a "wet roup." Dry roup is most likely a simple benign catarrh corresponding to the recurring croup affecting children, especially those inhabiting valleys and near a river bank. Wet roup, on the other hand, in its malignancy resembles diphtheria and membranous croup. 7. The micro-organism of roup (the wet variety or malignant variety) probably lives for a considerable time, at least, in the earth near the surface, and thus it is readily spread from animal to animal—as well as by direct contact with affected birds. 8. Conditions of soil and surroundings favorable to the spread of diphtheria would likewise appear to favor the spread of roup in fowls.

Annales de la Soc. Med.-Chir. de Liege, April.

Foreign Body in Maxillary Sinus. E. Gulikers.—A soldier fell from his bicycle while smoking a pipe, and for 1½ years afterward a slight swelling of the left malar region persisted, with a fistula at the point where the first upper bicuspid had been extracted six years before. The fistula into the maxillary sinus was enlarged and a fragment of the amber mouthpiece of a pipe, 5 cm. long by 1.4 wide, extracted. The sinus communicated with the nose, which explained its tolerance for the foreign body.

Forced Delivery in Eclampsia. Galhausen.—An experience with eleven cases of serious puerperal eclampsia treated by forced delivery after failure of other methods has convinced the writer that this is the only rational treatment in many cases. In one observation the eclampsia commenced at the fourth month of pregnancy. He observes that rapid digital dilation, combined with the use of forceps, is most effective, and that he has never known an eclamptic seizure to be induced by these maneuvers. When albuminuria and oliguria are not noted until after several attacks, the prognosis is more favorable than when they occur early.

Perforating Appendicitis in an Infant. Goyens.—An infant six weeks old, fed with boiled milk, suffered from diarrhea, and a tumor was noticed in the right inguinal region. The autopsy showed a gangrenous, perforated appendix with consequent peritoneal infection and septicemia.

Bulletin de la Soc. Med. des Hop. de Paris, June 14 to 28.

Nerve-Lesions in Zona. G. Ballet.—A female patient, 68 years of age, with primary zona or zoster fever, the cutaneous lesions localized on the left side of the neck, extending from the jaw to the upper part of the thoracic wall, died of a brief intercurrent pneumonia, which commenced on the nineteenth day. The posterior root of the third cervical nerve was found very much altered. The myelin was dissociated in fragments in some of the funiculi, with proliferation of the protoplasm; in others scarcely a trace of the myelin was to be seen, and no axis-cylinder. Some of the sheaths were entirely empty. The posterior root of the second cervical nerve presented similar, but much less intense, lesions, and the small cells of the corresponding portion of the posterior horn were atrophied and less numerous than on the other side.

Comprehensive Tests of "Varnish Gloves." Mariau.—Calmette devised a special apparatus for these tests of the varnish proposed by Mariau as a durable, flexible and effective covering for the hands of the surgeons—Soehnée Frères' white varnish, No. 3. A large box shaped like a desk, with the sloping portion of glass, contained a quart dish of bouillon and

Tonicity and Innervation of the Anal Sphincters. FRANKL-HOCHWART.—As the result of investigation of ninety-five dogs, the writer has established that anal continence depends to a large measure on a permanent muscular contraction not only of the striated internal, but also of the non-striated external sphincter. It is involuntary, but is dependent on the nervous system, although it does not degenerate after the nerve is severed, and resists the action of curare for an unusually long time. Constriction and dilatation occur even after complete destruction of the spinal cord, by stimulation of the inferior mesenteric ganglion, and even after this and the rectal nerves have all been severed, by the action of muscarin, annulled in turn by atropin.

Wiener Klinische Wochenschrift, June 28.

Trachea Tube. R. GERSUNY.—Nearly twenty years ago Gersuny published in the annual report of the Karolina Hospital the description of a trachea tube of his design, which was proved its usefulness more and more every year, but is only locally known. He, therefore, calls the attention of the profession at large to its superiority over the tubes generally in use. The chief improvement is the fact that it tapers below to one half the diameter of the upper portion, and that the opening is located exactly in the center of the trachea when inserted. The tube must be made of metal, but the higher initial cost of the metal is compensated by its durability. The upper portion fills the trachea completely and prevents the extension of the diphtheritic process or the passage of secretions into the organ. The incision required for its insertion is larger than usual, but this is of no importance and facilitates the reintroduction of the tube when taken out for any purpose; it is not necessary to have a second tube ready. There is no danger from pressure-necrosis, as the tapering tube does not come in contact with the walls of the trachea below. It is inserted with so little trouble that the internes accomplish it without assistance except from the nurse.

Fracture of the Bones of the Nose. K. BÜDINGER.—The method of treatment advocated for fractures of the upper portion of the nose—which are usually longitudinal, with a tendency of the fragments to lateral dislocation—is a median incision and reposition of the fragments, holding them in place with a few fine stitches. No time should be wasted in endeavors to replace them from within, nor with external application of plasters, etc.
